

# Modeling materials using density functional theory

John Kitchin

2012-07-11 Wed

## Contents

<b>1</b>	<b>Introduction to this book</b>	<b>6</b>
<b>2</b>	<b>TODO Introduction to DFT</b>	<b>8</b>
2.1	Recommended reading . . . . .	8
<b>3</b>	<b>Molecules</b>	<b>8</b>
3.1	Defining and visualizing molecules . . . . .	8
3.1.1	Predefined molecules . . . . .	9
3.1.2	Reading other data formats into a calculation . . . . .	12
3.1.3	From scratch . . . . .	13
3.2	. . . . .	17
3.2.1	Combining Atoms objects . . . . .	17
3.3	Simple properties . . . . .	18
3.3.1	Getting cartesian positions . . . . .	18
3.3.2	Molecular weight and molecular formula . . . . .	20
3.3.3	Center of mass . . . . .	20
3.3.4	Moments of inertia . . . . .	21
3.4	Simple properties that require computations . . . . .	22
3.4.1	Computing bond lengths and angles . . . . .	22
	Dihedral angles . . . . .	23
3.4.2	Energy and forces . . . . .	24
3.4.3	The density of states . . . . .	25
3.4.4	Visualizing electron density . . . . .	26
3.4.5	<b>TODO</b> Visualizing Kohn-Sham orbitals . . . . .	27
3.4.6	<b>TODO</b> Bader analysis . . . . .	27
3.4.7	Dipole moments . . . . .	27
3.4.8	<b>TODO</b> Atom-projected density of states . . . . .	29
3.5	Geometry optimization . . . . .	29

3.5.1	Bond lengths . . . . .	29
	Manual determination . . . . .	29
	Automatic geometry optimization with vasp . . . . .	31
3.6	Vibrational frequencies . . . . .	32
3.6.1	Manual calculation of vibrational frequency . . . . .	32
	<b>TODO</b> zero-point energy . . . . .	34
3.6.2	Automated vibrational calculations . . . . .	34
	Zero-point energy for multiple modes . . . . .	35
3.6.3	<b>TODO</b> Vibrations through ase . . . . .	36
3.7	Thermochemical properties of molecules . . . . .	36
3.8	Molecular reaction energies . . . . .	38
3.8.1	O2 dissociation . . . . .	38
	Simple estimate of O <sub>2</sub> dissociation energy . . . . .	38
	Estimating O <sub>2</sub> dissociation energy with spin polariza-	
	tion in triplet ground states . . . . .	39
	Looking at the two spin densities . . . . .	40
	Convergence study of the O <sub>2</sub> dissociation energy . . . .	41
	Illustration of the effect of sigma . . . . .	43
	<b>TODO</b> Estimating triplet oxygen dissociation energy	
	with low symmetry . . . . .	44
	Estimating singlet oxygen dissociation energy . . . . .	48
	Verifying the magnetic moments on each atom . . . . .	50
	<b>TODO</b> Using a different potential . . . . .	51
3.8.2	Water gas shift example . . . . .	52
3.8.3	Temperature dependent water gas shift equilibrium	
	constant . . . . .	54
	CO vibrations . . . . .	54
	CO2 vibrations . . . . .	55
	H2 vibrations . . . . .	55

## 1 Introduction to this book

This book serves two purposes: 1) to provide worked examples of using DFT to model materials properties, and 2) to provide references to more advanced treatments of these topics in the literature. It is not a definitive reference on density functional theory. Along the way to learning how to perform the calculations, you will learn how to analyze the data, make plots, and how to interpret the results. This book is very much “recipe” oriented, with the intention of giving you enough information and knowledge to start your research. In that sense, many of the computations are not publication quality with respect to convergence of calculation parameters.

You will read a lot of python code in this book. That is by design. I believe that computational work should always be scripted. That leaves a record of everything you did, so that you can reproduce it later, or report exactly what you did.

This book makes heavy use of many computational tools including:

- [Python](#)
  - [Module index](#)
- [Atomic Simulation Environment \(ase\)](#)

- [numpy](#)
- [scipy](#)
- [matplotlib](#)
- [emacs](#)
  - [org-mode](#) This book is written in org-mode, and is best read in emacs in org-mode. This format provides clickable links, easy navigation, syntax highlighting, as well as the ability to interact with the tables and code. The book is also available in pdf.
- [git](#) This book is available at <https://github.com/jkitchin/dft-book>
- [jasp](#)

jasp is a sophisticated wrapper to the `:mod:ase.calculators.vasp` python interface to the VASP calculator. It was written by me to facilitate writing this book, and to develop the best possible way to run DFT calculations. The best way to learn to use jasp is from this book. jasp is currently available at <https://bitbucket.org/jkitchin/jasp>. It probably requires the latest svn version of ase to work since I have been adding new functionality to `ase.calculators.vasp` as jasp is developed.

The goal in writing jasp was to create a computational environment where you write one script to create, run, and analyze your calculations. The code is smart, and submits jobs to a queue system when required, does not submit jobs more than once, allows many jobs to run in parallel, and gives you answers when available. jasp takes care of changing into Vasp calculation directories, and then changing back to where you started from. jasp has an interface to sqlite, and to version control (git) software. jasp has some features that `:mod:ase.calculators.vasp` does not have yet. They may get incorporated into ase one day.

jaspsum is a utility program provided in jasp which prints a pretty representation of the state of a calculation, plots the relaxation trajectory, or prints a code representation of a vasp directory.

It is not critical that you use jasp. You should be able to copy the actual VASP input files (which were generated by jasp) from a directory and simply run vasp. jasp is mostly compatible with `:mod:ase.calculators.vasp`, so you can replace this kind of code:

---

```
1 with jasp('directory', lotsofkeywords, atoms=atoms) as calc:
2     #do stuff
```

---

with this code:

---

```
1 CWD = os.getcwd()
2 os.chdir('directory')
3 calc=Vasp(lotsofkeywords)
4 atoms.set_calculator(calc)
5
6 try:
7     #do stuff
8 finally:
9     os.chdir(CWD)
```

---

The DFT code used primarily in this book is [Vasp](#).

- [Vasp wiki](#)
- [Vasp Manual](#)

Similar code would be used for other calculators, e.g. GPAW, Jacapo, etc... you would just have to import the python modules for those codes, and replace the code that defines the calculator.

## 2 TODO Introduction to DFT

All calculations were performed using VASP [22, 23, 25, 24], the Perdew-Burke-Ernzerhof (PBE) [37] exchange correlation functional with projector augmented wave (PAW) potentials provided in VASP [3, 26].

Monkhorst-Pack k-points [32]

PAW in GPAW [33]

## 3 Molecules

In this chapter we consider how to construct models of molecules, how to manipulate them, and how to calculate many properties of molecules.

### 3.1 Defining and visualizing molecules

We start by learning how to define a molecule and visualize it.

### 3.1.1 Predefined molecules

ASE defines a number of molecular geometries in the molecules database. Data for the G2 database are from Raghavachari, Redfern, and Pople, J. Chem. Phys. Vol. 106, 1063 (1997). See <http://chemistry.anl.gov/compmat/compterm.htm> for the original files.

All numbers are experimental values, except for coordinates, which are MP2(full)/6-31G(d) optimized geometries. Here is a list of all the species available in `mod:ase.data.g2`

---

```
1 from ase.data import g2
2 print g2.data.keys()
```

---

```
['isobutene', 'CH3CH2OH', 'CH3COOH', 'COF2', 'CH3NO2', 'CF3CN', 'CH3OH', 'CCH', 'CH3
```

Some other databases include the `mod:ase.data.s22` for weakly interacting dimers and complexes, and `mod:ase.data.extra_molecules` which has a few extras like biphenyl and C60.

Here is an example of getting the geometry of an acetonitrile molecule and writing an image to a file. Note that the default unit cell is a  $1\text{\AA}\times 1\text{\AA}\times 1\text{\AA}$  cubic cell. That is too small to use if your calculator uses periodic boundary conditions. We center the atoms in the unit cell and add vacuum on each side. We will add 6 Å of vacuum on each side. In the write command we use the option `show_unit_cell=2` to draw the unit cell boundaries

---

```
1 from ase import Atoms
2 from ase.data.molecules import molecule
3 from ase.io import write
4
5 c60 = molecule('CH3CN')
6
7 c60.center(vacuum=6)
8 print c60.get_cell()
9
10 write('molecules/ch3cn.png', c60, show_unit_cell=2)
```

---

```
[[ 13.775328  0.      0.      ]
 [  0.      13.537479  0.      ]
 [  0.      0.      15.014576]]
```

It is possible to rotate the atoms with `func:ase.io.write` if you wanted to see pictures from another angle. In the next example we rotate 45 degrees about the x-axis, then 45 degrees about the y-axis. Note that this only affects the image, not the actual coordinates

---

```
1 from ase import Atoms
2 from ase.data.molecules import molecule
3 from ase.io import write
4
5 atoms = molecule('CH3CN')
6
7 atoms.center(vacuum=6)
8 print atoms.get_cell()
9
10 write('molecules/ch3cn-rotated.png', atoms,
11       show_unit_cell=2, rotation='45x,45y,0z')
```

---

If you actually want to rotate the coordinates, there is a nice way to do that to, with the `func:ase.Atoms.rotate` method. Actually there are

Figure 1: The rotated version of CH<sub>3</sub>CN.

some subtleties in rotation. One rotates the molecule an angle (in radians) around a vector, but you have to choose whether the center of mass should be fixed or not. You also must decide whether the unit cell should be rotated or not. In the next example you can see the coordinates have changed due to the rotations.

---

```

1  from ase import Atoms
2  from ase.data.molecules import molecule
3  from ase.io import write
4  from numpy import pi
5
6  # ammonia
7  atoms = molecule('CH3CN')
8  p1 = atoms.get_positions()
9
10 atoms.rotate('x', pi/4, center='COM', rotate_cell=False)
11 atoms.rotate('y', pi/4, center='COM', rotate_cell=False)
12
13 write('molecules/ch3cn-rotated-2.png', atoms, show_unit_cell=2)
14 p2 = atoms.get_positions()
15 print p2 - p1

```

Figure 2: Rotated CH<sub>3</sub>CN molecule

Note in this last case the unit cell is oriented differently than the previous example, since we chose not to rotate the unit cell.

### 3.1.2 Reading other data formats into a calculation

ase.io.read supports reading in many different formats: Known formats:  
 ===== format  
 short name =====

GPAW restart-file gpw Dacapo netCDF output file dacapo Old ASE netCDF trajectory nc Virtual Nano Lab file vnl ASE pickle trajectory traj ASE bundle trajectory bundle GPAW text output gpaw-text CUBE file cube XCrySDen Structure File xsf Dacapo text output dacapo-text XYZ-file xyz VASP POSCAR/CONTCAR file vasp VASP OUTCAR file vasp\_out SIESTA STRUCT file struct\_out ABINIT input file abinit V\_Sim ascii file v\_sim Protein Data Bank pdb CIF-file cif FHI-aims geometry file aims FHI-aims output file aims\_out VTK XML Image Data vti VTK XML Structured Grid vts VTK XML Unstructured Grid vtu TURBOMOLE coord file tmol TURBOMOLE gradient file tmol-gradient exciting input exi Atom-Eye configuration cfg WIEN2k structure file struct DftbPlus input file dftb CASTEP geom file cell CASTEP output file castep CASTEP trajectory file geom ETSF format etsf.nc DFTBPlus GEN format gen CMR db/cmr-file db CMR db/cmr-file cmr LAMMPS dump file lammmps Gromacs coordinates gro =====

You can read xyz-coordinate files to create `mod:ase.Atoms` objects. Here is what an xyz file might look like:

Note that the xyz format does not have unit cell information in it, so you will have to figure out a way to provide it. In this example, we center the atoms in a box with vacuum on all sides.

---

```

1 from ase.io import read,write
2 import numpy as np
3
4 atoms = read('molecules/isobutane.xyz')
5 atoms.center(vacuum=5)
6 write('molecules/isobutane_xyz.png', atoms, show_unit_cell=2)

```

---

### 3.1.3 From scratch

When there is no data file for the molecule you want, or no database to get it from, you have to define your atoms geometry by hand. Here is how that is done.

---

```

1 from ase import Atoms, Atom
2 from ase.io import write
3
4 #method 1 - simple cubic unit cell
5 atoms = Atoms([Atom('C',[0., 0.,0.]),
6               Atom('O',[1.1,0.,0.])],
7               cell=(10,10,10))
8

```

---

Figure 3: An isobutane molecule read in from an xyz data file.

```
9  print 'V = %1.0f Ang^3' % atoms.get_volume()  
10  
11  write('molecules/simple-cubic-cell.png',atoms,show_unit_cell=2)
```

---

There are two inconvenient features of the simple cubic cell:

1. Since the CO atom is at the corner, its electron density is spread over the 8 corners of the box, which is not convenient for visualization later.
2. Due to the geometry of the cube, you need fairly large cubes to decouple the molecule from its images. Here, the CO molecule has 6 images due to periodic boundary conditions that are 10 angstroms away. The volume of the unit cell is  $1000 \text{ \AA}^3$ .

The first problem is easy to solve by centering the atoms in the unit cell. The second problem can be solved by using an fcc lattice. Below we show the result, where we have guessed values for  $b$  until the CO molecules are on average 10 angstroms apart. Note the final volume is only about  $715 \text{ \AA}^3$ , which is smaller than the cube. This will result in less computational time to compute properties.

---

```

1  from ase import Atoms, Atom
2  from ase.io import write
3
4  b = 7.1
5  atoms2 = Atoms([Atom('C',[0., 0.,0.]),
6                  Atom('O',[1.1,0.,0.])],
7                cell=[[b, b, 0.],
8                    [b, 0., b],
9                    [0., b, b]])
10 print 'V = %1.1f Ang^3' % atoms2.get_volume()
11
12 atoms2.center() #translate atoms to center of unit cell
13 write('molecules/fcc-cell.png',atoms2,show_unit_cell=2)

```

---

At this point you might ask “How do you know the distance to the neighboring image?” The `ag` viewer lets you compute this graphically, but we can use code to determine this too. All we have to do is figure out the length of each lattice vector. We use the `numpy` module to compute the distance of a vector as the square root of the sum of squared elements.

---

```

1  from ase import Atoms, Atom
2  import numpy as np
3
4  b = 7.1
5  atoms2 = Atoms([Atom('C',[0., 0.,0.]),
6                  Atom('O',[1.1,0.,0.])],
7                  cell=[[b, b, 0.],
8                        [b, 0., b],
9                        [0., b, b]])
10
11  # get unit cell vectors and their lengths
12  (a1, a2, a3) = atoms2.get_cell()
13  print '|a1| = %1.2f Ang' % np.sum(a1**2)**0.5
14  print '|a2| = %1.2f Ang' % np.sum(a2**2)**0.5
15  print '|a3| = %1.2f Ang' % np.sum(a3**2)**0.5

```

---

## 3.2

### 3.2.1 Combining Atoms objects

It is frequently useful to combine two Atoms objects, e.g. for computing reaction barriers, or other types of interactions. In ase, we simply add two Atoms objects together. Here is an example of getting an ammonia and oxygen molecule in the same unit cell.

---

```

1  from ase import Atoms
2  from ase.data.molecules import molecule
3  from ase.io import write
4
5  atoms1 = molecule('NH3')
6
7  atoms2 = molecule('O2')
8  atoms2.translate([3,0,0])
9
10 bothatoms = atoms1 + atoms2
11 bothatoms.center(5)
12
13 write('molecules/bothatoms.png', bothatoms, show_unit_cell=2, rotation='90x')

```

---

### 3.3 Simple properties

Simple properties do not require a DFT calculation. They are typically only functions of the atom types and geometries.

#### 3.3.1 Getting cartesian positions

If you want the x,y,z coordinates of the atoms, use the func:`ase.Atoms.get_positions`.

If you are interested in the fractional coordinates, use func:`ase.Atoms.get_scaled_positions`.

---

```

1 from ase import Atoms
2 from ase.data.molecules import molecule
3 from ase.io import write
4
5 atoms = molecule('C6H6')
6
7 # access properties on each atom
8 print ' # sym  p_x    p_y    p_z'
9 print '-----'
10 for i,atom in enumerate(atoms):
11     print '%3i%3s%8.2f%8.2f%8.2f' % (i,atom.symbol,atom.x,atom.y,atom.z)
12
13 # get all properties in arrays
14 sym = atoms.get_chemical_symbols()
```

```

15 pos = atoms.get_positions()
16 num = atoms.get_atomic_numbers()
17
18 atom_indices = range(len(atoms))
19
20 print
21 print '  # sym   at#      p_x      p_y      p_z'
22 print '-----'
23 for i,s,n,p in zip(atom_indices,sym,num,pos):
24     px,py,pz = p
25     print '%3i%3s%6i%10.2f%8.2f%8.2f' % (i,s,n,px,py,pz)

```

---

#	sym	p_x	p_y	p_z
0	C	0.00	1.40	0.00
1	C	1.21	0.70	0.00
2	C	1.21	-0.70	0.00
3	C	0.00	-1.40	0.00
4	C	-1.21	-0.70	0.00

### 3.3.2 Molecular weight and molecular formula

We can quickly compute the molecular weight of a molecule with this little recipe.

---

```
1  from ase import Atoms
2  from ase.data.molecules import molecule
3
4  atoms = molecule('C6H6')
5  masses = atoms.get_masses()
6
7  molecular_weight = sum(masses)
8
9  print 'The molecular weight of %s is %f' % (atoms.get_chemical_symbols(reduce=True),
10                                             molecular_weight)
```

---

The molecular weight of C6H6 is 78.113640

### 3.3.3 Center of mass

The center of mass is a helpful quantity to have for a variety of computations, including translating atoms for a rotation, etc... Here is an example of getting the center of mass from an Atoms object using `func:ase.Atoms.get_center_of_mass`.

$$\text{COM} = \frac{\sum m_i \cdot r_i}{\sum m_i}$$

---

```
1  from ase import Atoms
2  from ase.structure import molecule
3  from ase.io import write
4
5  # ammonia
6  atoms = molecule('NH3')
7
8  print atoms.get_center_of_mass() # cartesian coordinates
9
10 # compute the center of mass by hand
11 from ase.data import atomic_masses
12 import numpy as np
13 pos = atoms.positions
14 masses = atoms.get_masses()
15
16 COM = np.array([0., 0., 0.])
17 for m,p in zip(masses, pos):
18     COM += m*p
19 COM /= sum(masses)
20
21 print COM
22
23 # one-line linear algebra definition of COM
24 print np.dot(masses, pos)/np.sum(masses)
```

---

```
[ 0.00000000e+00  5.91843349e-08  4.75457009e-02]
[ 0.00000000e+00  5.91843349e-08  4.75457009e-02]
[ 0.00000000e+00  5.91843349e-08  4.75457009e-02]
```

### 3.3.4 Moments of inertia

func:ase.Atoms.get\_moments\_of\_inertia

---

```
1  from ase import *
2  from ase.structure import molecule
3  from ase.units import *
4
5  print 'linear rotors: I = [Ia Ia 0]'
6  atoms = molecule('CO2')
7  print ' CO2 moments of inertia: ',atoms.get_moments_of_inertia()
8  print
9
10 print 'symmetric rotors (IA = Ib) < Ic'
11 atoms = molecule('NH3')
12 print ' NH3 moments of inertia: ',atoms.get_moments_of_inertia()
13
14 atoms = molecule('C6H6')
15 print ' C6H6 moments of inertia: ',atoms.get_moments_of_inertia()
16 print
17
18 print 'symmetric rotors (IA = Ib) > Ic'
19 atoms = molecule('CH3Cl')
20 print 'CHCl3 moments of inertia: ',atoms.get_moments_of_inertia()
21 print
22
23 print 'spherical rotors Ia = Ib = Ic'
24 atoms = molecule('CH4')
25 print ' CH4 moments of inertia: ',atoms.get_moments_of_inertia()
26 print
27
28 print 'unsymmetric rotors Ia != Ib != Ic'
29 atoms = molecule('C3H7Cl')
30 print ' C3H7Cl moments of inertia: ',atoms.get_moments_of_inertia()
```

---

```
linear rotors: I = [Ia Ia 0]
CO2 moments of inertia: [ 0.          44.45384271  44.45384271]

symmetric rotors (IA = Ib) < Ic
NH3 moments of inertia: [ 1.71012426  1.71012548  2.67031768]
C6H6 moments of inertia: [ 88.77914641  88.77916799 177.5583144 ]

symmetric rotors (IA = Ib) > Ic
CHCl3 moments of inertia: [ 3.20372189 37.97009644 37.97009837]
```

```
spherical rotors Ia = Ib = Ic
CH4 moments of inertia: [ 3.19145621  3.19145621  3.19145621]

unsymmetric rotors Ia != Ib != Ic
CHFC1Br moments of inertia: [ 19.41351508  213.18961963  223.16255537]

mod:ase.structure.molecule
```

### 3.4 Simple properties that require computations

#### 3.4.1 Computing bond lengths and angles

It is a common to compute bond lengths. The Atoms object contains a `func:ase.Atoms.get_distance` method to make this easy. You have to specify the indices of the two atoms you want the distance between. Don't forget the indices start at 0.

---

```
1  from ase import Atoms
2  from ase.structure import molecule
3  from ase.io import write
4
5  # ammonia
6  atoms = molecule('NH3')
7
8  for i, atom in enumerate(atoms):
9      print '%2i %3s' % (i, atom.symbol)
10
11 # N-H bond length
12 print atoms.get_distance(0,1)
```

---

```
0  N
1  H
2  H
3  H
1.01679344636
```

Bond angles are a little trickier. We can use some simple trigonometry:  $a \cdot b = |a||b| \cos(\theta)$ , so we can calculate the angle as  $\theta = \arccos\left(\frac{a \cdot b}{|a||b|}\right)$ , we just have to define our two vectors  $a$  and  $b$ . We compute these vectors as the difference in positions of two atoms. For example, here we compute the angle H-N-H in an ammonia molecule. This is the angle between N-H1 and N-H2. In the next example, we utilize functions in numpy to perform the calculations, specifically the `arccos` function, the `dot` function, and `norm` functions.

---

```

1  from ase import Atoms
2  from ase.structure import molecule
3  from ase.io import write
4
5  # ammonia
6  atoms = molecule('NH3')
7
8  for i, atom in enumerate(atoms):
9      print '%2i %3s' % (i, atom.symbol)
10
11  a = atoms.positions[0] - atoms.positions[1]
12  b = atoms.positions[0] - atoms.positions[2]
13
14  from numpy import arccos, dot, pi
15  from numpy.linalg import norm
16
17  theta_rad = arccos(dot(a,b)/(norm(a)*norm(b))) # in radians
18
19  print 'theta = %1.1f degrees' % (theta_rad*180./pi)

```

---

```

0    N
1    H
2    H
3    H
theta = 106.3 degrees

```

Alternatively you could use the `func:ase.Atoms.get_angle`. Note we want the angle between atoms 1-0-2 to get the H-N-H angle.

---

```

1  from ase import Atoms
2  from ase.data.molecules import molecule
3  from numpy import pi
4  # ammonia
5  atoms = molecule('NH3')
6
7  print atoms.get_angle([1,0,2])*180./pi

```

---

```
106.334624232
```

**Dihedral angles** There is support in ase for computing [dihedral angles](#). Lets illustrate that for ethane. We will compute the dihedral angle between atoms 5, 1, 0, and 4. That is a H-C-C-H dihedral angle, and one can visually see (although not here) that these atoms have dihedral angle of  $60^\circ$ .

---

```

1  from ase import Atoms
2  from ase.structure import molecule

```

---

```

3  from ase.visualize import view
4  import numpy as np
5
6  atoms = molecule('C2H6')
7
8  for i, atom in enumerate(atoms):
9      print '%2i %3s' % (i,atom.symbol)
10
11  da = atoms.get_dihedral([5,1,0,4])*180./np.pi
12  print 'dihedral angle = %1.2f degrees' % da

```

---

```

0  C
1  C
2  H
3  H
4  H
5  H
6  H
7  H
dihedral angle = 60.00 degrees

```

### 3.4.2 Energy and forces

Two of the most important quantities we are interested in is the total energy and the forces on the atoms. To get these, we have to define a calculator and attach it to an `mod:ase.Atoms` object so that it knows how to get the data, and then a DFT calculation must be run.

Here is an example of getting the energy and forces from a CO molecule. The forces in this case are very high, indicating that this geometry is not close to the ground state geometry. Note that the forces are only along the x-axis, which is along the molecular axis.

---

```

1  #!/usr/bin/env python
2  from ase import Atoms, Atom
3  from jasp import *
4  import numpy as np
5  np.set_printoptions(precision=3, suppress=True)
6
7  co = Atoms([Atom('C', [0, 0, 0]),
8              Atom('O', [1.2, 0, 0])],
9            cell=(6., 6., 6.))
10
11  with jasp('molecules/simple-co', #output dir
12          xc='PBE',
13          nbands=6,
14          encut=350,
15          ismear=1,

```

```

16         sigma=0.01,
17         atoms=co):
18
19     print co.get_potential_energy()
20     print co.get_forces()

```

---

```

-14.687906
[[ 5.095  0.    0.   ]
 [-5.095  0.    0.   ]]

```

### 3.4.3 The density of states

---

```

1  #!/usr/bin/env python
2  from ase.dft.dos import *
3  from jasp import *
4  from pylab import *
5
6  with jasp('molecules/co-qn') as calc:
7      dos = DOS(calc)
8      plot(dos.get_energies(), dos.get_dos())
9      xlabel('Energy - $E_f$ (eV)')
10     ylabel('DOS')
11 savefig('images/co-dos.png')

```

---

### 3.4.4 Visualizing electron density

---

```
1  #!/usr/bin/env python
2  from enthought.mayavi import mlab
3  from jasp import *
4
5  with jasp('molecules/co-qn') as calc:
6      x,y,z,cd = calc.get_charge_density()
7
8  mlab.contour3d(x,y,z,cd)
9
10 mlab.savefig('images/co-cd.png')
11
12 mlab.show()
```

---

Figure 4: Charge density of a CO molecule with an atom at the origin. Due to periodic boundary conditions, part of the charge is at each corner of the unit cell.

---

```
1  #!/usr/bin/env python
2  from enthought.mayavi import mlab
3  from jasp import *
```

---

```

4
5 with jasp('molecules/co-centered') as calc:
6     x,y,z,cd = calc.get_charge_density()
7
8     mlab.contour3d(x,y,z,cd)
9
10    mlab.savefig('images/co-cd-centered.png')
11
12    mlab.show()

```

---

Figure 5: Charge density of a CO molecule centered in the unit cell.

### 3.4.5 TODO Visualizing Kohn-Sham orbitals

need to read wavecar files!

### 3.4.6 TODO Bader analysis

### 3.4.7 Dipole moments

---

```

1 from jasp import *
2 from ase.calculators.vasp import *

```

```

3  from ase.units import Debye
4  from ase import Atom, Atoms
5
6  atoms = Atoms([Atom('C',[2.422,0,0]),
7                 Atom('O',[3.578,0,0])],
8                cell=(10,10,10))
9
10 atoms.center()
11
12 with jasp('molecules/co-centered',
13          encut=350,
14          xc='PBE',
15          atoms=atoms) as calc:
16     atoms.get_potential_energy()
17

84
85     print 'The dipole moment is {0:1.2f}'.format(dipole_moment)

```

---

Note that a convenience function using the code above exists in jasp:

---

```

1  from jasp import *
2  from ase.units import Debye
3
4  with jasp('molecules/co-centered') as calc:
5      dipole_vector = calc.get_dipole_moment()
6      dipole_moment = ((dipole_vector**2).sum())**0.5/Debye
7      print 'The dipole moment is {0:1.2f} Debye'.format(dipole_moment)

```

---

### 3.4.8 TODO Atom-projected density of states

## 3.5 Geometry optimization

### 3.5.1 Bond lengths

**Manual determination** The equilibrium bond length of a CO molecule is approximately the bond length that minimizes the total energy. We can find that by computing the total energy as a function of bond length, and noting where the minimum is. Here is an example in vasp. There are a few features I would like to point out here. We want to compute 5 bond lengths,

and each calculation is independent of all the others. `:mod:jasp` is setup to automatically handle jobs for you by submitting them to the queue.

---

```

1  #!/usr/bin/env python
2  from ase import *
3  from jasp import *
4  import numpy as np
5  np.set_printoptions(precision=3,suppress=True)
6
7  bond_lengths = [1.05, 1.1, 1.15, 1.2, 1.25]

Bondlength = 1.14 angstroms

```

## 3.6 Vibrational frequencies

### 3.6.1 Manual calculation of vibrational frequency

The principle idea in calculating vibrational frequencies is that we consider a molecular system as masses connected by springs. If the springs are Hookean, e.g. the force is proportional to the displacement, then we can readily solve the equations of motion and find that the vibrational frequencies are related to the force constants and the masses of the atoms. For example, in a simple molecule like CO where there is only one spring, the frequency is:

$\nu = \frac{1}{2\pi} \sqrt{k/\mu}$  where  $\frac{1}{\mu} = \frac{1}{m_C} + \frac{1}{m_O}$  and  $k$  is the spring constant. We will compute the value of  $k$  from DFT calculations as follows:

$k = \frac{\partial^2 E}{\partial x^2}$  at the equilibrium bond length. We actually already have the data to do this from section [Manual determination](#). We only need to fit an equation to the energy vs. bond-length data, find the minimum energy bond-length, and then evaluate the second derivative of the fitted function at the minimum. We will use a cubic polynomial for demonstration here. Polynomials are numerically convenient because they are easy to fit, and it is trivial to get the roots and derivatives of the polynomials, as well as to evaluate them at other points.

---

```

1 from jasp import *
2 from ase.units import *
3
4 bond_lengths = [1.05, 1.1, 1.15, 1.2, 1.25]
5 energies = []
6
7 for d in bond_lengths:

```

```

8     with jasp('molecules/co-{0}'.format(d)) as calc:
9         atoms = calc.get_atoms()
10        energies.append(atoms.get_potential_energy())
11
12    # fit the data
13    pars = np.polyfit(bond_lengths, energies, 3)
14    xfit = np.linspace(1.05, 1.25)
15    efit = np.polyval(pars, xfit)
16
17    # first derivative
18    dpars = np.polyder(pars)
19    # find where the minimum is. chose the second one because it is the
20    # minimum we need.
21    print 'roots of first derivative are {0}'.format(np.roots(dpars))
22
23    d_min = 1.14425395
24    # second derivative
25    ddpars = np.polyder(dpars)
26
27    #curvature at minimum = force constant
28    k = np.polyval(ddpars, d_min)/kg*s**2
29
30    # reduced mass
31    from ase.data import atomic_masses
32    C_mass = atomic_masses[6]/kg
33    O_mass = atomic_masses[8]/kg
34
35    mu = (C_mass*O_mass)/(C_mass + O_mass)
36
37    frequency = 1./(2.*np.pi)*np.sqrt(k/mu)
38    print 'The CO vibrational frequency is {0} cm^{{-1}}'.format(frequency/3e10)
39
40    import matplotlib.pyplot as plt
41    plt.plot(bond_lengths, energies, 'bo ')
42    plt.plot(xfit, efit, 'b-')
43    plt.xlabel('Bond length ($\AA$)')
44    plt.ylabel('Total energy (eV)')
45    plt.show()

```

---

This result is in good agreement with [experiment](#). The procedure used above is how many vibrational calculations are done. With more atoms, you have to determine a force constant matrix and diagonalize it. For more details, see [7]. In practice, we usually allow a packaged code to automate this, which we cover in the next section.

We now consider how much energy is in this vibration. This is commonly called zero-point energy (ZPE) and it is defined as  $E_{ZPE} = \frac{1}{2}h\nu$  for a single mode.

---

```

1  c = 3e10 # speed of light cm/s
2  h = 4.135667516e-15 # eV/s
3

```

```

4 nu = 2143.6076625*c # 1/s
5
6 E_zpe = 0.5*h*nu
7
8 print 'E_ZPE = {0:1.3f} eV'.format(E_zpe)

```

---

E\_ZPE = 0.133 eV

This is a reasonable amount of energy! Zero-point energy increases with increasing vibrational frequency.

A final note is that this analysis is in the “harmonic approximation”. The frequency equation is the solution to a harmonic oscillator. If the spring is non-linear, then there are anharmonic effects that may become important, especially at higher temperatures.

**TODO zero-point energy**  $E_{ZPE} = \frac{1}{2}h\nu$

### 3.6.2 Automated vibrational calculations

Vasp has built-in capability for performing vibrational calculations.

---

```

1 #adapted from http://cms.mpi.univie.ac.at/wiki/index.php/H2O_vibration
2 from ase import Atoms, Atom
3 from jasp import *
4
5 atoms = Atoms([Atom('H',[0.5960812, -0.7677068, 0.0000000]),
6                  Atom('O',[0.0000000, 0.0000000, 0.0000000]),
7                  Atom('H',[0.5960812, 0.7677068, 0.0000000])),
8               cell=(8,8,8))
9
10 with jasp('molecules/h2o_vib',
11           xc='PBE',
12           encut=400,
13           ismear=0, # Gaussian smearing
14           ibrion=6, # finite differences with symmetry
15           nfree=2, # central differences (default)
16           potim=0.015, # default as well
17           ediff=1e-8,
18           nsw=1,
19           atoms=atoms) as calc:
20
21     print atoms.get_forces()
22     print calc.get_vibrational_frequencies()

```

---

```

[[ 0.006474 -0.021573 -0.001509]
 [-0.012948 0.         0.003019]
 [ 0.006474 0.021573 -0.001509]]
[3836.1533119999999, 3722.659114, 1583.004226, 35.64620899999999, 21.37895100000000]

```

Note we get 9 frequencies here. Water has 3 atoms, with three degrees of freedom each. Three of those degrees of freedom are translations, and three are rotations. That leaves  $3N-6 = 3$  degrees of vibrational freedom. The modes of water vibration are (with our calculated values in parentheses):

1. a symmetric stretch at  $3657 \text{ cm}^{-1}$  (3723)
2. an asymmetric stretch at  $3756 \text{ cm}^{-1}$  (3836)
3. and a bending mode at  $1595 \text{ cm}^{-1}$  (1583)

<http://webbook.nist.gov/cgi/cbook.cgi?ID=C7732185&Mask=800#Electronic-Spec>

The results are not too far off, and more accurate frequencies may be possible using tighter tolerance on `POTIM`, or by using `IBRION=7` or `8`.

Note: the `calc.get_vibrational_frequencies()` is only available in jasp (7/12/2012).

**Zero-point energy for multiple modes** For a molecule with lots of vibrational modes the zero-point energy is defined as the sum over all the vibrational modes:

$$E_{ZPE} = \sum_i \frac{1}{2} h \nu_i$$

Here is an example for water. Note we do not sum over the imaginary modes. We should also ignore the rotational and translational modes (some of those are imaginary, but some are just small).

---

```

1 from jasp import *
2 import numpy as np
3 c = 3e10 # speed of light cm/s
4 h = 4.135667516e-15 # eV/s
5
6 # first, get the frequencies.
7 with jasp('molecules/h2o_vib') as calc:
8     freq = calc.get_vibrational_frequencies()
9
10 ZPE = 0.0
11 for f in freq:
12     if not isinstance(f, float):
13         continue # skip complex numbers
14     nu = f*c # convert to frequency
15     ZPE += 0.5*h*nu
16
17 print 'The ZPE of water is {0:1.3f} eV'.format(ZPE)
18
19 # one liner
20 ZPE = np.sum([0.5*h*f*c for f in freq if isinstance(f, float)])
21 print 'The ZPE of water is {0:1.3f} eV'.format(ZPE)

```

---

Note the zero-point energy of water is also fairly high. That is because of the high frequency O-H stretches.

### 3.6.3 TODO Vibrations through ase

must set JASPRC['mode']='run' and submit the job to the queue. Also, clone the directory because we will be throwing away the results.

## 3.7 Thermochemical properties of molecules

ase provides a [thermochemistry](#) module.

---

```
1 from ase.structure import molecule
2 from ase.thermochemistry import IdealGasThermo
3 from jasp import *
4
5 atoms = molecule('N2')
6 atoms.set_cell((10,10,10), scale_atoms=False)
7
8 # first we relax a molecule
9 with jasp('molecules/n2-relax',
10          xc='PBE',
11          encut=300,
12          ibrion=2,
13          nsw=5,
14          atoms=atoms) as calc:
15
16     electronicenergy = atoms.get_potential_energy()
17
18 # next, we get vibrational modes
19 with jasp('molecules/n2-vib',
20          xc='PBE',
21          encut=300,
22          ibrion=6,
23          nfree=2,
24          potim=0.15,
25          nsw=1,
26          atoms=atoms) as calc:
27     calc.calculate()
28     vib_freq = calc.get_vibrational_frequencies() # in cm-1
29
30     #convert wavenumbers to energy
31     h = 4.1356675e-15 # eV*s
32     c = 3.0e10 #cm/s
33     vib_energies = [h*c*nu for nu in vib_freq]
34     print vib_energies
35
36 # # now we can get some properties. Note we only need one vibrational
37 # energy since there is only one mode. This example does not work if
38 # you give all the energies because one energy is zero.
39 thermo = IdealGasThermo(vib_energies=vib_energies[0:0],
40                          electronicenergy=electronicenergy, atoms=atoms,

## 3.8 Molecular reaction energies

### 3.8.1 O2 dissociation

The first reaction we consider is a simple dissociation of oxygen molecule into two oxygen atoms:  $O_2 \rightarrow 2O$ . The dissociation energy is pretty straightforward to define: it is the energy of the products minus the energy of the reactant.  $D = 2 * E_O - E_{O_2}$ . It would appear that we simply calculate the energy of an oxygen atom, and an oxygen molecule and evaluate the formula. Let's do that.

#### Simple estimate of O<sub>2</sub> dissociation energy

---

```
1 from jasp import *
2 from ase import Atom, Atoms
3
4 atoms = Atoms([Atom('O',[5,5,5])],
5               cell=(10,10,10))
6
7 with jasp('molecules/O',
8           xc='PBE',
9           encut=400,
10          ismear=0,
11          atoms=atoms) as calc:
12     try:
13         E_O = atoms.get_potential_energy()
14     except (VaspSubmitted, VaspQueued):
15         E_O = None
16
17 # now relaxed O2 dimer
18
19 atoms = Atoms([Atom('O',[5,5,5]),
20               Atom('O',[6.22, 5,5])],
21               cell=(10,10,10))
22
23 with jasp('molecules/O2',
24          xc='PBE',
25          encut=400,
26          ismear=0,
27          ibrion=2, # make sure we relax the geometry
28          nsw=10,
29          atoms=atoms) as calc:
30     try:
31         E_O2 = atoms.get_potential_energy()
32     except (VaspSubmitted, VaspQueued):
33         E_O2 = None
34
35 if None not in (E_O, E_O2):
36     print 'O2 -> 2O D = {0:1.3f} eV'.format(2*E_O - E_O2)
```

---

The answer we have obtained is way too high! Experimentally the dissociation energy is more like 5.2 eV (need reference).

We implicitly neglected spin-polarization in the example above. That could be a problem, since the  $O_2$  molecule can be in one of two spin states, a singlet or a triplet, and these should have different energies. Furthermore, the oxygen atom can be a singlet or a triplet, and these would have different energies. To account for spin polarization, we have to tell Vasp to use spin-polarization, and give initial guesses for the magnetic moments of the atoms. Let's try again with spin polarization.

**Estimating  $O_2$  dissociation energy with spin polarization in triplet ground states** To tell Vasp to use spin-polarization we use `INCAR=2`, and we set initial guesses for magnetic moments on the atoms with the `magmom` keyword. In a triplet state there are two electrons with spins of the same sign.

---

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  atoms = Atoms([Atom('O',[5,5,5],magmom=2)],
5                cell=(10,10,10))
6
7  with jasp('molecules/O-sp-triplet',
8            xc='PBE',
9            encut=400,
10           ismear=0,
11           ispin=2,
12           atoms=atoms) as calc:
13      try:
14          E_0 = atoms.get_potential_energy()
15      except (VaspSubmitted, VaspQueued):
16          E_0 = None
17
18  print 'Magnetic moment on O = {0} Bohr magnetons'.format(atoms.get_magnetic_moment())
19
20  # now relaxed O2 dimer
21  atoms = Atoms([Atom('O',[5,5,5],magmom=1),
22                Atom('O',[6.22, 5,5],magmom=1)],
23                cell=(10,10,10))
24
25  with jasp('molecules/O2-sp-triplet',
26            xc='PBE',
27            encut=400,
28            ismear=0,
29            ispin=2, # turn spin-polarization on
30            ibrion=2, # make sure we relax the geometry
31            nsw=10,
32            atoms=atoms) as calc:
33      try:
34          E_02 = atoms.get_potential_energy()
35      except (VaspSubmitted, VaspQueued):
36          E_02 = None

```

```

37
38 # verify magnetic moment
39 print 'Magnetic moment on O2 = {0} Bohr magnetons'.format(atoms.get_magnetic_moment())
40
41 if None not in (E_0, E_O2):
42     print 'O2 -> 20 D = {0:1.3f} eV'.format(2*E_0 - E_O2)

```

---

This is much closer to accepted literature values for the DFT-GGA O<sub>2</sub> dissociation energy. It is still more than 1 eV above an experimental value, but most of that error is due to the GGA exchange correlation functional. Some additional parameters that might need to be checked for convergence are the SIGMA value (it is probably too high for a molecule), as well as the cutoff energy. Oxygen is a “hard” atom that requires a high cutoff energy to achieve high levels of convergence.

**Looking at the two spin densities** In a spin-polarized calculation there are actually two electron densities: one for spin-up and one for spin-down. We will look at the differences in these two through the density of states.

---

```

1 from jasp import *
2 from ase.dft.dos import *
3
4 with jasp('molecules/O2-sp-triplet') as calc:
5     dos = DOS(calc, width=0.2)
6     d_up = dos.get_dos(spin=0)
7     d_down = dos.get_dos(spin=1)
8     e = dos.get_energies()
9
10 ind = e <= 0.0
11 # integrate up to 0eV
12 print 'number of up states = {0}'.format(np.trapz(d_up[ind],e[ind]))
13 print 'number of down states = {0}'.format(np.trapz(d_down[ind],e[ind]))
14
15 import pylab as plt
16 plt.plot(e, d_up, e, -d_down)
17 plt.xlabel('energy [eV]')
18 plt.ylabel('DOS')
19 plt.legend(['up', 'down'])
20 plt.savefig('images/O2-sp-dos.png')

```

---

You can see there are two different densities of states for the two spins. One has 7 electrons in it, and the other has 5 electrons in it. The difference of two electrons leads to the magnetic moment of 2 which we calculated earlier.

### Convergence study of the O<sub>2</sub> dissociation energy

48 plt.ylabel('O2 dissociation energy (eV)')
49 plt.savefig('images/O2-dissociation-convergence.png')

```

---

Based on these results, you could argue the dissociation energy is converged to about 2 meV at a planewave cutoff of 450 eV, and within 50 meV at 350 eV cutoff. You have to decide what an appropriate level of convergence is. Note that increasing the planewave cutoff significantly increases the computational time, so you are balancing level of convergence with computational speed. It would appear that planewave cutoff is not the cause for the discrepancy between our calculations and literature values.

---

7         if 'Total CPU time used (sec)' in line:
8             print '{0}: {1}'.format(encut, line)
9     f.close()

```

---

**Illustration of the effect of sigma** We were not careful in selecting a good value for **SIGMA** in the calculations above. The default value of SIGMA is 0.2, which may be fine for metals, but it is not correct for molecules. SIGMA is the broadening factor used to smear the electronic density of states at the Fermi level. For a metal with a continuous density of states, this appropriate, but for molecules with discrete energy states it does not make sense. We are somewhat forced to use the machinery designed for metals on molecules. The solution is to use a very small SIGMA. Ideally you would use SIGMA=0, but that is not practical for convergence reasons, so we try to find what is small enough.

Let us examine the effect of SIGMA on the dissociation energy here.

---

Clearly SIGMA has an effect, but it does not move the dissociation energy closer to the literature values!

**TODO Estimating triplet oxygen dissociation energy with low symmetry** It has been suggested that breaking spherical symmetry of the atom can result in lower energy of the atom. The symmetry is broken by putting the atom off-center in a box. We will examine the total energy of an oxygen atom in a few geometries. First, let us consider variations of a square box.

---

Figure 6: Effect of SIGMA on the oxygen dissociation energy.

```

1  from jasp import *
2  from ase import Atom, Atoms

50     except (VaspSubmitted, VaspQueued):
51         pass

```

---

There is no difference of significance in these energies. The origin and center are identical (by symmetry too). The meV variation in the random position is probably only due to the atom being off the fft grid points a little bit.

Now, let's consider some non-square boxes.

---

```

49         except (VaspSubmitted, VaspQueued):
50             pass

```

---

This is a surprisingly large difference in energy! Nearly 0.4 eV. This is precisely the amount of energy we were in disagreement with the literature values. Surprisingly, the “random” position is higher in energy, similar to the cubic boxes. Finally, we put this all together. We use a non-symmetric box for the O-atom

---

```

1  from jasp import *
2  from ase import Atom, Atoms
3

43         print 'E_0: ',E_0
44         print 'O2 -> 2O   D = {0:1.3f} eV'.format(2*E_0 - E_O2)

```

---

This actually agrees within 30-50 meV of reported literature values. Note that with a different “random” position, we get the lower energy for the O atom. All the disagreement we had been seeing was apparently in the O atom energy. So, if you don’t need D in your analysis, you will not see the error. Also note that this error is specific to there being a spherical atom in a symmetric cell. This is not a problem for most molecules.

**Estimating singlet oxygen dissociation energy** Finally, let us consider the case where each species is in the singlet state.

---

```

1     from jasp import *
2     from ase import Atom, Atoms
3
4     atoms = Atoms([Atom('O',[5,5,5],magmom=0)],
5                   cell=(10,10,10))
6
7     with jasp('molecules/O-sp-singlet',
8              xc='PBE',
9              encut=400,
10             ismear=0,
11             ispin=2,
12             atoms=atoms) as calc:
13         try:

```

```

14         E_0 = atoms.get_potential_energy()
15     except (VaspSubmitted, VaspQueued):
16         E_0 = None
17
18     print 'Magnetic moment on O = {0} Bohr magnetons'.format(atoms.get_magnetic_moment())
19
20     # now relaxed O2 dimer
21     atoms = Atoms([Atom('O',[5,5,5],magmom=1),
22                   Atom('O',[6.22, 5,5],magmom=-1)],
23                  cell=(10,10,10))
24
25     with jasp('molecules/O2-sp-singlet',
26              xc='PBE',
27              encut=400,
28              ismear=0,
29              ispin=2, # turn spin-polarization on
30              ibrion=2, # make sure we relax the geometry
31              nsw=10,
32              atoms=atoms) as calc:
33         try:
34             E_O2 = atoms.get_potential_energy()
35         except (VaspSubmitted, VaspQueued):
36             E_O2 = None
37
38     # verify magnetic moment
39     print atoms.get_magnetic_moment()
40
41     if None not in (E_0, E_O2):
42         print 'O2 -> 2O D = {0:1.3f} eV'.format(2*E_0 - E_O2)

```

---

Interestingly, Vasp still found a triplet spin state on the oxygen atom, even though we guessed an initial magnetic moment of 0. This highlights a difficulty in computing magnetic moments: you provide an initial guess and a solution is found. The magnetic moment of a singlet state is zero, so the molecule is correct. Also interesting is that the dissociation energy is almost equal to the experimental value. This is probably a coincidence, and may reflect the fact that the singlet oxygen state is less stable than the triplet state. Let us directly compare their total energies:

---

```

1 from jasp import *
2
3 with jasp('molecules/O2-sp-singlet') as calc:
4     print calc.get_atoms().get_potential_energy()
5
6 with jasp('molecules/O2-sp-triplet') as calc:
7     print calc.get_atoms().get_potential_energy()

```

---

You can see here the triplet state has an energy that is 1 eV more stable than the singlet state.

**Verifying the magnetic moments on each atom** It is one thing to see the total magnetic moment of a singlet state, and another to ask what are the magnetic moments on each atom. In vasp you must use [LORBIT=11](#) to get the magnetic moments of the atoms written out.

---

```

1 from jasp import *
2 from ase import Atom, Atoms
3
4 with jasp('molecules/O2-sp-singlet') as calc:
5     calc.clone('molecules/O2-sp-singlet-magmoms')
6
7 with jasp('molecules/O2-sp-singlet-magmoms') as calc:
8     calc.set(lorbit=11)
9     atoms = calc.get_atoms()
10    magmoms = atoms.get_magnetic_moments()
11
12    print 'singlet ground state'
13    for i,atom in enumerate(atoms):
14        print 'atom {0}: magmom = {1}'.format(i, magmoms[i])
15    print atoms.get_magnetic_moment()
16
17 with jasp('molecules/O2-sp-triplet') as calc:
18     calc.clone('molecules/O2-sp-triplet-magmoms')
19
20 with jasp('molecules/O2-sp-triplet-magmoms') as calc:
21     calc.set(lorbit=11)
22     atoms = calc.get_atoms()
23     magmoms = atoms.get_magnetic_moments()
24     print
25     print 'triplet ground state'
26     for i,atom in enumerate(atoms):
27         print 'atom {0}: magmom = {1}'.format(i, magmoms[i])
28     print atoms.get_magnetic_moment()

```

---

```

singlet ground state
atom 0: magmom = 0.0
atom 1: magmom = 0.0
0.0

```

```

triplet ground state
atom 0: magmom = 0.815
atom 1: magmom = 0.815
2.0000084

```

Note the atomic magnetic moments do not add up to the total magnetic moment. The atomic magnetic moments are not really true observable properties. The moments are determined by a projection method that probably involves a spherical orbital, so the moments may be over or underestimated.

**TODO Using a different potential** It is possible we need a higher quality potential to get the 6.02 eV value quoted by many. Here we try the O\_sv potential, which treats the 1s electrons as valence electrons. Note however, the ENMIN in the POTCAR is very high!

---

```

1  grep ENMIN $VASP_PP_PATH/potpaw_PBE/O_sv/POTCAR

```

---

```

36             E_02 = atoms.get_potential_energy()
37         except (VaspSubmitted, VaspQueued):
38             E_02 = None
39
40     # verify magnetic moment
41     print 'Magnetic moment on O2 = {0} Bohr magnetons'.format(atoms.get_magnetic_moment())
42
43     if None not in (E_0, E_02):
44         print 'O2 -> 2O   D = {0:1.3f} eV'.format(2*E_0 - E_02)

```

---

### 3.8.2 Water gas shift example

We consider calculating the reaction energy of the water-gas shift reaction in this example.

We define the reaction energy as the difference in energy between the products and reactants.

$$\Delta E = E_{\text{CO}_2} + E_{\text{H}_2} - E_{\text{CO}} - E_{\text{H}_2\text{O}}$$

For now, we compute this energy simply as the difference in DFT energies. In the next section we will add zero-point energies and compute the energy difference as a function of temperature. For now, we simply need to compute the total energy of each molecule in its equilibrium geometry.

---

```
1 from ase.data.molecules import molecule
2 from jasp import *
3 JASPRC['queue.walltime'] = '1:00:00'
4
5 # first we define our molecules. These will automatically be at the coordinates from the G2 database.
6
7 CO = molecule('CO')
8 CO.set_cell([8,8,8], scale_atoms=False)
9
10 H2O = molecule('H2O')
11 H2O.set_cell([8,8,8], scale_atoms=False)
12
13 CO2 = molecule('CO2')
14 CO2.set_cell([8,8,8], scale_atoms=False)
15
16 H2 = molecule('H2')
17 H2.set_cell([8,8,8], scale_atoms=False)
18
19 # now the calculators to get the energies
20 with jasp('molecules/wgs/CO',

72         print '\Delta E = {0:1.3f} eV'.format(dE)
73         print '\Delta E = {0:1.3f} kcal/mol'.format(dE*23.06035)
74         print '\Delta E = {0:1.3f} kJ/mol'.format(dE*96.485)

```

---

We [estimated](#) the enthalpy of this reaction at standard conditions to be -41 kJ/mol, which is a fair bet lower than we estimated. In the next section we will examine whether additional corrections are needed, such as zero-point and temperature corrections.

It is a good idea to verify your calculations and structures are what you expected. Let us print them here. Inspection of these results shows the geometries were all relaxed.

---

```

1 from jasp import *
2
3 print '**** calculation summaries'
4 print '***** CO'
5 with jasp('molecules/wgs/CO') as calc:
6     print '##begin_example'

26     print '##end_example'

```

---

### 3.8.3 Temperature dependent water gas shift equilibrium constant

To correct the reaction energy for temperature effects, we must compute the vibrational frequencies of each species, and estimate the temperature dependent contributions to vibrational energy and entropy. We will break these calculations into several pieces. First we do each vibrational calculation. After those are done, we can get the data and construct the thermochemistry objects we need to estimate the reaction energy as a function of temperature (at constant pressure).

#### CO vibrations

---

```

1 from jasp import *
2 JASPRC['queue.walltime'] = '1:00:00'
3
4 # get relaxed geometry
5 with jasp('molecules/wgs/CO') as calc:
6     CO = calc.get_atoms()
7
8 # now do the vibrations
9 with jasp('molecules/wgs/CO-vib',
10         xc='PBE',
11         encut=350,
12         ismear=0,
13         ibrion=6,
14         nfree=2,
15         potim=0.02,
16         nsw=1,
17         atoms=CO) as calc:
18     calc.calculate()

```

```
19     vib_freq = calc.get_vibrational_frequencies()
20     print vib_freq
```

---

CO has only one vibrational mode.

## CO2 vibrations

---

```
1  from jasp import *
2  JASPRC['queue.walltime'] = '1:00:00'
3
4  # get relaxed geometry
5  with jasp('molecules/wgs/CO2') as calc:
6      CO2 = calc.get_atoms()
7
8  # now do the vibrations
9  with jasp('molecules/wgs/CO2-vib',
10         xc='PBE',
11         encut=350,
12         ismear=0,
13         ibrion=6,
14         nfree=2,
15         potim=0.02,
16         nsw=1,
17         atoms=CO2) as calc:
18      calc.calculate()
19      vib_freq = calc.get_vibrational_frequencies()
20      print vib_freq
```

---

CO2 is a linear molecule with  $3N-5 = 4$  vibrational modes. They are the first four frequencies.

## H2 vibrations

---

```
1  from jasp import *
2  JASPRC['queue.walltime'] = '1:00:00'
3
4  # get relaxed geometry
5  with jasp('molecules/wgs/H2') as calc:
6      H2 = calc.get_atoms()
7
8  # now do the vibrations
9  with jasp('molecules/wgs/H2-vib',
10         xc='PBE',
11         encut=350,
12         ismear=0,
13         ibrion=6,
14         nfree=2,
15         potim=0.02,
16         nsw=1,
17         atoms=H2) as calc:
18      calc.calculate()
```

```
19     vib_freq = calc.get_vibrational_frequencies()
20     print vib_freq
```

---

There is only one frequency of importance (the one at  $4281\text{ cm}^{-1}$ ) for the linear H2 molecule.

## H2O vibrations

---

```
1  from jasp import *
2  JASPRC['queue.walltime'] = '1:00:00'
3
4  # get relaxed geometry
5  with jasp('molecules/wgs/H2O') as calc:
6      H2O = calc.get_atoms()
7
8  # now do the vibrations
9  with jasp('molecules/wgs/H2O-vib',
10          xc='PBE',
11          encut=350,
12          ismear=0,
13          ibrion=6,
14          nfree=2,
15          potim=0.02,
16          nsw=1,
17          atoms=H2O) as calc:
18      calc.calculate()
19      vib_freq = calc.get_vibrational_frequencies()
20      print vib_freq
```

---

Water has  $3N-6 = 3$  vibrational modes.

**TODO thermochemistry** Now we are ready. We have the electronic energies and vibrational frequencies of each species in the reaction.

---

```
1  from ase.thermochemistry import IdealGasThermo
2  from jasp import *
3  import numpy as np
4  import matplotlib.pyplot as plt
5
6  # first we get the electronic energies
7  with jasp('molecules/wgs/CO') as calc:
8      CO = calc.get_atoms()
9      E_CO = CO.get_potential_energy()
10
11  with jasp('molecules/wgs/CO2') as calc:
12      CO2 = calc.get_atoms()
13      E_CO2 = CO2.get_potential_energy()
14
15  with jasp('molecules/wgs/H2') as calc:
16      H2 = calc.get_atoms()
```

```

17     E_H2 = H2.get_potential_energy()
18
19     with jasp('molecules/wgs/H2O') as calc:
20         H2O = calc.get_atoms()
21         E_H2O = H2O.get_potential_energy()
22
23     # now we get the vibrational energies
24     h = 4.1356675e-15 # eV*s
25     c = 3.0e10 # cm/s
26
27     with jasp('molecules/wgs/CO-vib') as calc:
28         vib_freq = calc.get_vibrational_frequencies()
29         CO_vib_energies = [h*c*nu for nu in vib_freq]
30
31     with jasp('molecules/wgs/CO2-vib') as calc:
32         vib_freq = calc.get_vibrational_frequencies()

81 plt.legend(loc='best')
82 plt.savefig('images/wgs-dG-T.png')
83
84 plt.figure()
85 R = 8.314e-3 # gas constant in kJ/mol/K
86
87 Keq = np.exp(-Grxn/R/Trange)
88 plt.plot(Trange, Keq)
89 plt.ylim([0, 100])
90 plt.xlabel('Temperature (K)')
91 plt.ylabel('$K_{eq}$')
92 plt.savefig('images/wgs-Keq.png')
93 plt.show()

```

---

You

can see a few things here. One is that at near 298K, the Gibbs free energy is about -40 kJ/mol. This is too negative for a standard state free energy, which we estimated to be about -29 kJ/mol from the [Nist webbook](#). There could be several reasons for this disagreement, but the most likely one is errors in the exchange-correlation functional. Second, it appears the reaction enthalpy gets slightly more exothermic with temperature. This does

not seem correct.

At 1000K we estimate the Gibbs free energy to be about -4 kJ/mol, compared to about -3 kJ/mol estimated from the Nist webbook.

Despite the error in  $\Delta G$ , the equilibrium constant at 1000K seems reasonable. If you zoom in to 1000K you find the  $K_{eq}$  is about 1.5, and it is known to be 1.44 (see [this example](#)).

**TODO something is wrong with the thermochemistry I think.**

### 3.9 TODO Molecular reaction barriers

#### 3.10 Simulated infrared spectra

At <http://homepage.univie.ac.at/david.karhanek/downloads.html#Entry02> there is a recipe for computing the Infrared vibrational spectroscopy intensities in Vasp. We are going to do that for water here. First, we will relax a water molecule.

---

```
1 from ase import Atoms, Atom
2 from jasp import *
3
4 atoms = Atoms([Atom('H', [0.5960812, -0.7677068, 0.0000000]),
5               Atom('O', [0.0000000, 0.0000000, 0.0000000]),
6               Atom('H', [0.5960812, 0.7677068, 0.0000000])],
```

```

7         cell=(8,8,8))
8
9     with jasp('molecules/h2o_relax',
10              xc='PBE',
11              encut=400,
12              ismear=0, # Gaussian smearing
13              ibrion=2,
14              ediff=1e-8,
15              nsw=10,
16              atoms=atoms) as calc:
17
18     print atoms.get_forces()

```

---

```

[[ 0.00033 -0.000422  0.      ]
 [-0.00066  0.        0.      ]
 [ 0.00033  0.000422  0.      ]]

```

Next, we instruct Vasp to compute the vibrational modes using density functional perturbation theory with IBRION=7. Note, this is different than in [Vibrational frequencies](#) where finite differences were used.

---

```

1  from ase import Atoms, Atom
2  from jasp import *
3
4  #read in relaxed geometry
5  with jasp('molecules/h2o_relax') as calc:
6      atoms = calc.get_atoms()
7
8  # now define a new calculator
9  with jasp('molecules/h2o_vib_dfpt',
10           xc='PBE',
11           encut=400,
12           ismear=0, # Gaussian smearing
13           ibrion=7, # switches on the DFPT vibrational analysis (with no symmetry constraints)
14           nfree=2,
15           potim=0.015,
16           lepsilon=True, # enables to calculate and to print the BEC tensors
17           lreal=False,
18           nsw=1,
19           nwrite=3, # affects OUTCAR verbosity: explicitly forces SQRT(mass)-divided eigenvectors to be printed
20           atoms=atoms) as calc:
21      calc.calculate(atoms)

```

---

To analyze the results, this shell script was provided to extract the results.

---

```

1  #!/bin/bash
2  # A utility for calculating the vibrational intensities from VASP output (OUTCAR)
3  # (C) David Karhanek, 2011-03-25, ICIQ Tarragona, Spain (www.iciq.es)

```

```

8  awk -v max="$max" '{print $1,$2,$3/max}' temp.reform.res.txt > exact.reform.res.txt
9  awk -v max="$max" '{printf "%03u %6.1f %5.3f\n",$1,$2,$3/max}' temp.reform.res.txt > reform.res.txt
10 printf " ..done\n..normal modes:\n"
11 rm temp.reform.res.txt
12 cat reform.res.txt
13 cd ../../

```

---

```

..reformatting and normalizing intensities ..done
..normal modes:
001 3827.3 0.726
002 3713.0 0.019
003 1587.2 1.000

```

The interpretation of these results is that the mode at  $3713\text{ cm}^{-1}$  would be nearly invisible in the IR spectrum. Earlier we interpreted that as the symmetric stretch. In this mode, there is only a small change in the molecule dipole moment, so there is a small IR intensity.

**3.10.1 TODO** Shell scripts are rough. One day I should rewrite this in python.

**3.11** Bader analysis

[28]

## 4 Bulk systems

See this paper (<http://arxiv.org/pdf/1204.2733.pdf>) for a very informative comparison of DFT codes for computing different bulk properties.

### 4.1 Defining and visualizing bulk systems

#### 4.1.1 Built-in functions in ase

---

```
1 from ase.io import write
2 from ase.lattice.cubic import FaceCenteredCubic
3
4
5 atoms = FaceCenteredCubic(directions=[[1,0,0],
6                                     [0,1,0],
7                                     [0,0,1]],
8                             size=(1,1,1),
9                             symbol='Ag',
10                             latticeconstant=4.0)
11
12 write('images/Ag-bulk.png',atoms,show_unit_cell=2)
13
14 # to make an alloy, we can replace one atom with another kind
15 atoms[0].symbol = 'Pd'
16 write('images/AgPd-bulk.png',atoms,show_unit_cell=2)
```

---

#### 4.1.2 Using <http://materialsproject.org>

The [Materials Project](http://materialsproject.org) offers web access to a pretty large number of materials (over 21,000 at the time of this writing), including structure and other computed properties. You must sign up for an account at the website, and then you can access the information. You can search for materials with lots of different criteria including formula, unit cell formula, by elements, by structure, etc... The website allows you to download the VASP files used to create the calculations. They also develop the [pymatgen](https://pymatgen.org/) project (which requires python 2.7+).

For example, I downloaded this cif file for a RuO<sub>2</sub> structure (Material ID 825).

```

---

```

1 from ase.io import read, write
2
3 atoms = read('bulk/Ru2O4_1.cif')
4
5 write('images/Ru2O4.png', atoms, show_unit_cell=2)

```

---

You can also download the VASP files. I have copied these files to a directory, and now we can run a calculation as:

---

```
1 from jasp import *
2 JASPRC['mode'] = 'run'
3
4 with jasp('bulk/Ru204',
5          xc='PBE',
6          setups={'Ru': '_pv'}) as calc:
7     atoms = calc.get_atoms()
```

```
8     atoms.get_potential_energy()
9     print calc
```

---

Some notes: we had to specify the PBE functional. That is not a default, and not specifying it currently leads to errors in not finding the potentials.

We get exactly the same result as the website! Why is this helpful then? Well, we could use this as a starting point to look at an equation of state, or to plot some interesting electronic structure,... Or we can gain a little confidence that our version of Vasp is working like the one they used.

## 4.2 Determining bulk structures

### 4.2.1 fcc/bcc crystal structures

The fcc and bcc structures are simple. They only have one degree of freedom: the lattice constant. In this section we show how to calculate the equilibrium volume of each structure, and determine which one is more stable. We start with the fcc crystal structure of Cu. We will manually define the crystal structure based on the definitions in Kittel [19] (Chapter 1).

---

```
1  from jasp import *
2  from ase import Atom, Atoms
3
4  # fcc
5  LC = [3.5, 3.55, 3.6, 3.65, 3.7, 3.75]
6  fcc_energies = []
7  for a in LC:
8      atoms = Atoms([Atom('Cu', (0,0,0))],
9                    cell=0.5*a*np.array([[1.0, 1.0, 0.0],
10                                         [0.0, 1.0, 1.0],
11                                         [1.0, 0.0, 1.0]]))
12
13     with jasp('bulk/Cu-{0}'.format(a),
14              xc='PBE',
15              encut=350,
16              kpts=(8,8,8),
17              atoms=atoms) as calc:
18         e = atoms.get_potential_energy()
19         fcc_energies.append(e)
20
21  import matplotlib.pyplot as plt
22  plt.plot(LC, fcc_energies)
23  plt.xlabel('Lattice constant ($\AA$)')
24  plt.ylabel('Total energy (eV)')
25  plt.savefig('images/Cu-fcc.png')
```

---

If you want to know the lattice constant that gives the lowest energy, you would fit an [equation of state](#) to the data. Here is an example:

---

```

1  from jasp import *
2  from ase.utils.eos import *
3  LC = [3.5, 3.55, 3.6, 3.65, 3.7, 3.75]
4  energies = []
5  volumes = []
6  for a in LC:
7      with jasp('bulk/Cu-{}'.format(a)) as calc:
8          atoms = calc.get_atoms()
9          volumes.append(atoms.get_volume())
10         energies.append(atoms.get_potential_energy())
11
12  eos = EquationOfState(volumes, energies)
13  v0, e0, B = eos.fit()
14
15  print v0, e0, B
16
17  eos.plot('images/Cu-fcc-eos.png')
```

---

Before we jump into the bcc calculations, let's consider what range of lattice constants we should choose. The fcc lattice is close-packed, and the volume of the primitive cell is  $V = 1/4a^3$  or about 11.8 Å<sup>3</sup>/atom. The volume of the equilibrium bcc primitive cell will probably be similar to that. The question is: what bcc lattice constant gives that volume? The simplest way to answer this is to compute the answer using ase. We will make a bcc crystal at the fcc lattice constant, and then compute the scaling factor needed to make it the right volume.

---

```

1 from ase import Atom, Atoms
2
3 a = 3.61
4
5 atoms = Atoms([Atom('Cu', [0,0,0])],
6               cell=0.5*a*np.array([[1.0, 1.0, -1.0],
7                                   [-1.0, 1.0, 1.0],
8                                   [1.0, -1.0, 1.0]]))
9
10 print a*(11.8/atoms.get_volume())**(1./3.)

```

---

Now we run the equation of state calculations.

---

```

1 from jasp import *
2 JASPRC['mode'] = 'run'
3 from ase import Atom, Atoms
4
5 LC = [2.75, 2.8, 2.85, 2.9, 2.95, 3.0]
6

```

---

```

7  for a in LC:
8      atoms = Atoms([Atom('Cu', [0,0,0])],
9                      cell=0.5*a*np.array([[1.0, 1.0, -1.0],
10                                           [-1.0, 1.0, 1.0],
11                                           [1.0, -1.0, 1.0]]))
12
13
14      with jasp('bulk/Cu-bcc-{0}'.format(a),
15                xc='PBE',
16                encut=350,
17                kpts=(8,8,8),
18                atoms=atoms) as calc:
19          e = atoms.get_potential_energy()

```

---

Finally, we will compare the two crystal structures.

---

```

1  from jasp import *
2
3  bcc_LC = [2.75, 2.8, 2.85, 2.9, 2.95, 3.0]
4  bcc_volumes = []
5  bcc_energies = []
6  for a in bcc_LC:
7      with jasp('bulk/Cu-bcc-{0}'.format(a)) as calc:
8          atoms = calc.get_atoms()
9          bcc_volumes.append(atoms.get_volume())
10         bcc_energies.append(atoms.get_potential_energy())
11
12  # fcc
13  fcc_LC = [3.5, 3.55, 3.6, 3.65, 3.7, 3.75]
14  fcc_volumes = []
15  fcc_energies = []
16  for a in fcc_LC:
17      with jasp('bulk/Cu-{0}'.format(a)) as calc:
18          atoms = calc.get_atoms()
19          fcc_volumes.append(atoms.get_volume())
20          fcc_energies.append(atoms.get_potential_energy())
21
22  import matplotlib.pyplot as plt
23  plt.plot(fcc_volumes, fcc_energies, label='fcc')
24  plt.plot(bcc_volumes, bcc_energies, label='bcc')
25
26  plt.xlabel('Atomic volume ($\text{\AA}^3/\text{atom}$)')
27  plt.ylabel('Total energy (eV)')
28  plt.legend()
29  plt.savefig('images/Cu-bcc-fcc.png')
30  plt.show()

```

---

Note we plot the energy vs. atomic volume. That is because the lattice constants of the two crystal structures are very different. It also shows that the atomic volumes in the two structures are similar.

What can we say here? The fcc structure has a lower energy than the bcc structure, so we can conclude the fcc structure is more favorable. In

fact, the fcc structure is the experimentally found structure for Cu. Some caution is in order; if you run these calculations at a  $4 \times 4 \times 4$  k-point grid, the bcc structure is more stable because the results are not converged!

What can we say about the relative stability of fcc to hcp? Nothing, until we calculate the hcp equation of state.

#### 4.2.2 hcp

---

```

1  from ase.lattice.hexagonal import HexagonalClosedPacked
2  from jasp import *
3  import matplotlib.pyplot as plt
4
5  atoms = HexagonalClosedPacked(symbol='Ru',
6                                latticeconstant={'a':2.7, 'c/a':1.584})
7
8  a_list = [2.5, 2.6, 2.7, 2.8, 2.9]
9  covera_list = [1.4, 1.5, 1.6, 1.7, 1.8]
10
11 for a in a_list:
12     energies = []
13     for covera in covera_list:
14
15         atoms = HexagonalClosedPacked(symbol='Ru',
16                                         latticeconstant={'a':a, 'c/a':covera})
17
18         wd = 'bulk/Ru/{0:1.2f}-{1:1.2f}'.format(a,covera)
19
20         with jasp(wd,
21                   xc='PBE',
22                   kpts=(6,6,4),
23                   encut=350,
24                   atoms=atoms) as calc:
25             try:
26                 energies.append(atoms.get_potential_energy())
27             except (VaspSubmitted, VaspQueued):
28                 pass
29     plt.plot(covera_list, energies, label='a={0}'.format(a))
30
31 plt.xlabel('$c/a$ ($AA$)')
32 plt.ylabel('Energy (eV)')
33 plt.legend()
34 plt.savefig('images/Ru-covera-scan.png')

```

---

It looks like there is a minimum in the  $a=2.7$  Å curve, at a  $c/a$  ratio of about 1.6. We can look at the same data in a contour plot which shows more clearly there is minimum in all directions near that point.

---

```

1  from jasp import *
2  import matplotlib.pyplot as plt
3  from pylab import *
4
5  x = [2.5, 2.6, 2.7, 2.8, 2.9]
6  y = [1.4, 1.5, 1.6, 1.7, 1.8]
7
8  X,Y = meshgrid(x,y)
9  Z = np.zeros(X.shape)
10
11 for i,a in enumerate(x):
12     for j,covera in enumerate(y):
13
14         wd = 'bulk/Ru/{0:1.2f}-{1:1.2f}'.format(a,covera)
15
16         with jasp(wd) as calc:
17             atoms = calc.get_atoms()
18             try:
19                 Z[i][j] = atoms.get_potential_energy()
20             except (VaspSubmitted, VaspQueued):
21                 pass
22
23 cf = plt.contourf(X,Y,Z,20,
24                  cmap=cm.jet)
25
```

```

### 4.2.3 complex structures with internal degrees of freedom

A unit cell has six degrees of freedom: the lengths of each unit cell vector, and the angle between each vector. There may additionally be internal degrees of freedom for the atoms. It is impractical to try the approach used for Ru on anything complicated.

1. With the atoms frozen find the volume (at constant shape) that minimizes the total energy. The goal here is to just get an idea of where the right volume is.
2. Perform a volume equation of state calculation where each calculation is at constant volume, but the shape is allowed to change.

3. Finally, do a final calculation near the minimum energy allowing the volume to also change.

This multistep process is pretty reasonable to get a converged structure pretty quickly.

---

```

1  from ase import *
2  import numpy as np
3  from jasp import *
4  import matplotlib.pyplot as plt
5
6  '''
7  create a TiO2 structure from the lattice vectors at
8  http://cst-www.nrl.navy.mil/lattice/struk/c4.html
9  '''
10 a = 4.59 # experimental degrees of freedom.
11 c = 2.96
12 u = 0.3 #internal degree of freedom!
13
14 #primitive vectors
15 a1 = a*np.array([1.0, 0.0, 0.0])
16 a2 = a*np.array([0.0, 1.0, 0.0])
17 a3 = c*np.array([0.0, 0.0, 1.0])
18
19 atoms = Atoms([Atom('Ti',[0., 0., 0.]),
20               Atom('Ti',0.5*a1 + 0.5*a2 + 0.5*a3),
21               Atom('O',u*a1+u*a2),
22               Atom('O',-u*a1 -u*a2),
23               Atom('O',(0.5+u)*a1 + (0.5-u)*a2 + 0.5*a3),
24               Atom('O',(0.5-u)*a1 + (0.5+u)*a2 + 0.5*a3)],
25               cell=[a1,a2,a3])
26
27 v0 = atoms.get_volume()
28 cell0 = atoms.get_cell()
29
30 factors = [0.9, 0.95, 1.0, 1.05, 1.1] #to change volume by
31
32 energies, volumes = [], []
33 for f in factors:
34     v1 = f*v0
35     cell_factor = (v1/v0)**(1./3.)
36
37     atoms.set_cell(cell0*cell_factor, scale_atoms=True)
38
39     with jasp('bulk/tio2/step1-{0:1.2f}'.format(f),
40              encut=350,
41              kpts=(4,4,4),
42              xc='PBE',
43              sigma=0.05,
44              atoms=atoms) as calc:
45         try:
46             energies.append(atoms.get_potential_energy())
47             volumes.append(atoms.get_volume())
48         except (VaspSubmitted, VaspQueued):

```

```

49         pass
50
51     plt.plot(volumes, energies)
52     plt.xlabel('Vol. ( $\text{\AA}^3$ )')
53     plt.ylabel('Total energy (eV)')
54     plt.savefig('images/tio2-step1.png')

```

---

In step 2 we will actually do some relaxations. We will do a series of relaxations, from 62 to 66  $\text{\AA}^3$ , and allow the ions and cell shape to relax (ISIF=4) at constant volume.

---

```

1  from jasp import *
2  import matplotlib.pyplot as plt
3
4  JASPRC['queue.walltime'] = '10:00'
5
6  with jasp('bulk/tio2/step1-1.00') as calc:
7      atoms = calc.get_atoms()
8      v0 = atoms.get_volume()
9      cell0 = atoms.get_cell()
10
11
12  volumes = [62., 63., 64., 65., 66.]
13
14  energies = []
15  for v in volumes:
16      atoms.set_cell((v/v0)**(1./3.)*cell0, scale_atoms=True)
17      with jasp('bulk/tio2/step2-{0}'.format(v),

```

```

18         encut=350,
19         kpts=(4,4,4),
20         xc='PBE',
21         sigma=0.05,
22         isif=4,      # relax ions, cell shape. not volume
23         ibrion=2,
24         nsw=10,
25         atoms=atoms) as calc:
26     try:
27         energies.append(atoms.get_potential_energy())
28     except (VaspSubmitted, VaspQueued):
29         pass
30
31 plt.plot(volumes, energies)
32 plt.xlabel('Vol. ( $\text{\AA}^3$ )')
33 plt.ylabel('Total energy (eV)')
34 plt.savefig('images/tio2-step2.png')

```

---

Now, we take the final step, with ISIF=3 using the best guess from step 2.

---

```

1 from jasp import *
2
3 with jasp('bulk/tio2/step2-64.0') as calc:
4     atoms = calc.get_atoms()
5
6 with jasp('bulk/tio2/step3',
7         encut=350,

```

```

8         kpts=(4,4,4),
9         xc='PBE',
10        sigma=0.05,
11        isif=3,      # relax ions, cell shape, and volume
12        ibrion=2,
13        nsw=10,
14        atoms=atoms) as calc:
15    try:
16        calc.calculate()
17        print calc
18    except (VaspSubmitted, VaspQueued):
19        pass
20
21 from pyspglib import spglib
22 print '\nThe spacegroup is {0}'.format(spglib.get_spacegroup(atoms))

```

---

The points to note here are the following:

1. The stress on the unit cell is very low.
2. The forces on the atoms are very small (less than 0.0 eV/Å).
3. The agreement with experimental lattice parameters is pretty good.
4. The spacegroup is still correct.

## 4.3 Bulk calculation parameters

### 4.3.1 Effect of SIGMA

In the self-consistent cycle of a DFT calculation, the total energy is minimized with respect to occupation of the Kohn-Sham orbitals. At absolute zero, a band is either occupied or empty. This discrete occupation results in discontinuous changes in energy with changes in occupation, which makes it difficult to converge. One solution is to artificially broaden the band occupancies, as if they were occupied at a higher temperature where partial occupation is possible. This results in a continuous dependence of energy on the partial occupancy, and dramatically increases the rate of convergence. **SIGMA** and **ISMear** affect how the partial occupancies of the bands are determined.

Some rules to keep in mind:

1. The smearing methods were designed for metals. For molecules, semi-conductors and insulators you should use a very small SIGMA (e.g. 0.01).

2. Standard values for metallic systems is SIGMA=0.1, but the best SIGMA may be [material specific](#).

---

```
1 from jasp import *
2 from ase import Atom, Atoms
3 import matplotlib.pyplot as plt
4
5 a = 3.61
6 atoms = Atoms([Atom('Cu', (0,0,0))],
7               cell=0.5*a*np.array([[1.0, 1.0, 0.0],
8                                   [0.0, 1.0, 1.0],
9                                   [1.0, 0.0, 1.0]]).repeat((2,2,2))
10
11 SIGMA = [0.001, 0.05, 0.1, 0.2, 0.5]
12
13 for sigma in SIGMA:
14     with jasp('bulk/Cu-sigma-{0}'.format(sigma),
15             xc='PBE',
16             encut=350,
17             kpts=(4,4,4),
18             ismear=-1,
19             sigma=sigma,
20             nbands=9*8,
21             atoms=atoms) as calc:
22         e = atoms.get_potential_energy()
23
24         nbands = calc.nbands
25         nkpts = len(calc.get_ibz_k_points())
26
27         occ = np.zeros((nkpts, nbands))
28         for i in range(nkpts):
29             occ[i,:] = calc.get_occupation_numbers(kpt=i)
30
31         max_occ = np.max(occ,axis=0) #axis 0 is columns
32
33         plt.plot(range(nbands), max_occ, label='$\sigma = {0}$'.format(sigma))
34
35
36 plt.xlabel('band number')
37 plt.ylabel('maximum occupancy (electrons)')
38 plt.ylim([-0.1, 2.1])
39 plt.legend(loc='best')
40 plt.savefig('images/occ-sigma.png')
41 plt.show()
```

---

## 4.4 Cohesive energy

The cohesive energy is defined as the energy to separate neutral atoms in their ground electronic state from the solid at 0K at 1 atm. We will compute this rhodium. Rh is normally an fcc metal, so we will use that and let Vasp find the equilibrium volume for us.

---

```

1 from jasp import *
2 from ase.lattice.cubic import FaceCenteredCubic
3 from ase import Atoms, Atom
4 # bulk system
5 atoms = FaceCenteredCubic(directions=[[0,1,1],
6                                     [1,0,1],
7                                     [1,1,0]],
8                             size=(1,1,1),
9                             symbol='Rh')
10
11 with jasp('bulk/bulk-rh',
12          xc='PBE',
13          encut=350,
14          kpts=(4,4,4),
15          isif=3,
16          ibrion=2,
17          nsw=10,
18          atoms=atoms) as calc:
19     bulk_energy = atoms.get_potential_energy()
20
21 # atomic system
22 atoms = Atoms([Atom('Rh',[5,5,5])],
23              cell=(7,8,9))
24
25 with jasp('bulk/atomic-rh',
26          xc='PBE',
27          encut=350,
28          kpts=(1,1,1),
29          atoms=atoms) as calc:
30     atomic_energy = atoms.get_potential_energy()
31
32 cohesive_energy = atomic_energy - bulk_energy
33 print 'The cohesive energy is {0:1.3f} eV'.format(cohesive_energy)

```

---

According to Kittel, the cohesive energy of Rh is 5.75 eV. There are a few reasons we may have discrepancy here:

1. The k-point grid used in the bulk state is not very dense. However, you can see below that the total energy is pretty converged by a  $6 \times 6 \times 6$   $k$ -point grid.

---

```

1 from jasp import *
2
3 with jasp('bulk/bulk-rh') as calc:
4     atoms = calc.get_atoms()
5
6
7 kpts = [3, 4, 6, 9, 12, 15, 18]
8
9 for k in kpts:
10     with jasp('bulk/bulk-rh-kpts-{0}'.format(k),
11             xc='PBE',

```

```

12         encut=350,
13         kpts=(k,k,k),
14         atoms=atoms) as calc:
15     e = atoms.get_potential_energy()
16
17     print '{0:2d}, {0:2d}, {0:2d}): total energy = {1} eV'.format(k,e)

```

---

1. We neglected spin on the atomic state. Rh in the atomic state has this electronic structure: [Kr] 4d8 5s1 and is a doublet. We will examine this next.

---

```

1  from jasp import *
2  JASPRC['mode'] = 'run'
3  from ase.lattice.cubic import FaceCenteredCubic
4  from ase import Atoms, Atom
5  # bulk system
6  atoms = FaceCenteredCubic(directions=[[0,1,1],
7                                       [1,0,1],
8                                       [1,1,0]],
9                              size=(1,1,1),
10                             symbol='Rh')
11
12  with jasp('bulk/bulk-rh',
13            xc='PBE',
14            encut=350,
15            kpts=(4,4,4),
16            isif=3,
17            ibrion=2,
18            nsw=10,
19            atoms=atoms) as calc:
20      bulk_energy = atoms.get_potential_energy()
21
22  # atomic system
23  atoms = Atoms([Atom('Rh',[5,5,5],magmom=1)],
24               cell=(7,8,9))
25
26  with jasp('bulk/atomic-rh-sp',
27            xc='PBE',
28            encut=350,
29            kpts=(1,1,1),
30            ispin=2,
31            atoms=atoms) as calc:
32      atomic_energy = atoms.get_potential_energy()
33
34  cohesive_energy = atomic_energy - bulk_energy
35  print 'The cohesive energy is {0:1.3f} eV'.format(cohesive_energy)

```

---

Again, the value in Kittel [19] is 5.75 eV which is very close to this value.

## 4.5 Effect of pressure on phase stability

So far we have only considered relative stability at a pressure of 0 Pa. We now consider the relative stability of two phases under pressure. We will consider TiO<sub>2</sub> in the rutile and anatase phases.

The pressure is defined by:  $P = -\frac{\partial E}{\partial V}_T$

so if we have an equation of state  $E(V)$  we can calculate the pressure at any volume, or alternatively, given a pressure, compute the volume. Pressure can affect the energy of two phases differently, so that one may become stable under pressure. The condition where a phase transition occurs is when the pressure in the two phases is the same, which occurs at a common tangent.

Here is an example of that.

60 plt.savefig('images/rutile-anatase-eos.png')

```

---

To find the conditions where a phase transition occurs, we have to find the common tangent line between the rutile and anatase phases. In other words we have to solve these two equations:

$$(E_{\text{anatase}}(V_1) - E_{\text{rutile}}(V_2))/(V_1 - V_2) = P_{\text{anatase}}(V_1) = P_{\text{rutile}}(V_2)$$

This is a nonlinear algebra problem.

---

```

40 plt.xlabel('Volume ($\text{\AA}^3/\text{f.u.})$')
41 plt.ylabel('Total energy (eV/f.u.)')
42 plt.savefig('images/eos-common-tangent.png')

```

---

At a pressure of 4.5 GPa, we expect that anatase will start converting into rutile. Along this common tangent, a mixture of the two phases will be more stable than either pure phase.

## 4.6 Bulk reaction energies

### 4.6.1 Alloy formation energies

In this section we will consider how to calculate the formation energy of an fcc Cu-Pd alloy and how to use that information to discuss relative stabilities.

#### Basic alloy formation energy

---

```

1 from jasp import *
2 JASPRC['mode']='run'
3 from ase import Atom, Atoms
4
5 atoms = Atoms([Atom('Cu', [0.000, 0.000, 0.000])],
6               cell= [[ 1.818, 0.000, 1.818],
7                     [ 1.818, 1.818, 0.000],
8                     [ 0.000, 1.818, 1.818]])
9
10 with jasp('bulk/alloy/cu',
11          xc='PBE',
12          encut=350,
13          kpts=(13,13,13),
14          nbands=9,
15          ibrion=2,
16          isif=4,
17          nsw=10,
18          atoms=atoms) as calc:
```

```

19     cu = atoms.get_potential_energy()
20
21
22     atoms = Atoms([Atom('Pd', [0.000, 0.000, 0.000])),
23                   cell=[[ 1.978, 0.000, 1.978],
24                         [ 1.978, 1.978, 0.000],
25                         [0.000, 1.978, 1.978]])
26
27
28     with jasp('bulk/alloy/pd',
29               xc='PBE',
30               encut=350,
31               kpts=(13,13,13),
32               nbands=9,
33               ibrion=2,
34               isif=4,
35               nsw=10,
36               atoms=atoms) as calc:
37         pd = atoms.get_potential_energy()
38
39     print cu, pd

```

---

Note that the Pd energy is more negative than the Cu energy. This does not mean anything significant. We cannot say Pd is more stable than Cu; it is not like Cu could transmute into Pd!

---

```

1  from jasp import *
2  JASPRC['mode']='run'
3  from ase import Atom, Atoms
4
5  atoms = Atoms([Atom('Cu', [0.000, 0.000, 0.000]),
6                  Atom('Pd', [-1.652, 0.000, 2.039])),
7              cell= [[ 0.000, -2.039, 2.039],
8                    [ 0.000, 2.039, 2.039],
9                    [-3.303, 0.000, 0.000]])
10
11  with jasp('bulk/alloy/cupd-1',
12            xc='PBE',
13            encut=350,
14            kpts=(12,12,8),
15            nbands=17,
16            ibrion=2,
17            isif=4,
18            nsw=10,
19            atoms=atoms) as calc:
20      cupd1 = atoms.get_potential_energy()
21
22
23  atoms = Atoms([Atom('Cu', [-0.049, 0.049, 0.049]),
24                  Atom('Cu', [-11.170, 11.170, 11.170]),
25                  Atom('Pd', [-7.415, 7.415, 7.415]),
26                  Atom('Pd', [-3.804, 3.804, 3.804])),
27              cell=[[-5.629, 3.701, 5.629 ],
28                    [-3.701, 5.629, 5.629 ],

```

```

29             [-5.629, 5.629, 3.701]])
30
31 with jasp('bulk/alloy/cupd-2',
32           xc='PBE',
33           encut=350,
34           kpts=(8,8,8),
35           nbands=34,
36           ibrion=2,
37           isif=4,
38           nsw=10,
39           atoms=atoms) as calc:
40     cupd2 = atoms.get_potential_energy()
41
42 print cupd1, cupd2

```

---

Looking at these energies, you could be tempted to say cupd-2 is more stable than cupd-1 because its energy is much lower. This is wrong, however, because cupd-2 has twice as many atoms as cupd-1. We should compare the normalized total energies.

---

```

1 from jasp import *
2
3 with jasp('bulk/alloy/cupd-1') as calc:
4     atoms = calc.get_atoms()
5     e1 = atoms.get_potential_energy()/len(atoms)
6
7 with jasp('bulk/alloy/cupd-2') as calc:
8     atoms = calc.get_atoms()
9     e2 = atoms.get_potential_energy()/len(atoms)
10
11 print 'cupd-1: {0} eV/atom'.format(e1)
12 print 'cupd-2: {0} eV/atom'.format(e2)

```

---

After normalizing by number of atoms, we can see that cupd-1 is a more stable structure. However, we are looking at total energies, and we might ask: is cupd-1 more stable than a mixture of the parent compounds, fcc Cu and Pd?

---

```

1 from jasp import *
2
3 with jasp('bulk/alloy/cu') as calc:
4     atoms = calc.get_atoms()
5     cu = atoms.get_potential_energy()/len(atoms)
6
7 with jasp('bulk/alloy/pd') as calc:
8     atoms = calc.get_atoms()
9     pd = atoms.get_potential_energy()/len(atoms)
10
11
12 with jasp('bulk/alloy/cupd-1') as calc:

```

```

13     atoms = calc.get_atoms()
14     e1 = atoms.get_potential_energy()
15     for atom in atoms:
16         if atom.symbol == 'Cu':
17             e1 -= cu
18         else:
19             e1 -= pd
20     e1 /= len(atoms)
21
22 with jasp('bulk/alloy/cupd-2') as calc:
23     atoms = calc.get_atoms()
24     e2 = atoms.get_potential_energy()
25     for atom in atoms:
26         if atom.symbol == 'Cu':
27             e2 -= cu
28         else:
29             e2 -= pd
30     e2 /= len(atoms)
31
32 print 'Delta Hf cupd-1 = {0:1.2f} eV/atom'.format(e1)
33 print 'Delta Hf cupd-2 = {0:1.2f} eV/atom'.format(e2)

```

---

The answer is yes. Both structures are energetically more favorable than an equal composition mixture of the parent metals. The heat of formation for both structures is exothermic, but the cupd-1 structure is more stable than the cupd-2 structure. This is shown conceptually in Figure 7.

We will now examine another structure at another composition and its stability.

---

```

1 from jasp import *
2 JASPRC['mode']='queue'
3 from ase import Atom, Atoms
4
5 # parent metals
6 with jasp('bulk/alloy/cu') as calc:

8     cu = atoms.get_potential_energy()/len(atoms)
9
10 with jasp('bulk/alloy/pd') as calc:
11     atoms = calc.get_atoms()
12     pd = atoms.get_potential_energy()/len(atoms)
13
14 atoms = Atoms([Atom('Cu', [-3.672, 3.672, 3.672]),
15                Atom('Cu', [0.000, 0.000, 0.000]),
16                Atom('Cu', [-10.821, 10.821, 10.821]),
17                Atom('Pd', [-7.246, 7.246, 7.246])],
18               cell=[[-5.464, 3.565, 5.464],
19                     [-3.565, 5.464, 5.464],
20                     [-5.464, 5.464, 3.565]])
21
22 with jasp('bulk/alloy/cu3pd-1',
23          xc='PBE',

```

Figure 7: Conceptual picture of two alloys with exothermic formation energies.

```

24         encut=350,
25         kpts=(8,8,8),
26         nbands=34,
27         ibrion=2,
28         isif=4,
29         nsw=10,
30         atoms=atoms) as calc:
31     e3 = atoms.get_potential_energy()
32     for atom in atoms:
33         if atom.symbol == 'Cu':
34             e3 -= cu
35         else:
36             e3 -= pd
37     e3 /= len(atoms)
38     print 'Delta Hf cu3pd-1 = {0:1.2f} eV/atom'.format(e3)

```

The formation energy is slightly exothermic, which means the structure is more stable than a mixture of the parent metals. However, let us consider whether the structure is stable with respect to phase separation into pure Cu and the cupd-1 structure. We define the following quantities:

$$H_{f,Cu} = 0.0 \text{ eV/atom}, x_0 = 0 \quad H_{f,cupd-1} = -0.12 \text{ eV/atom}, x_3 = 0.5$$

The composition weighted average at  $x_{Pd} = 0.25$  is:

$$H_f = H_{f,Cu} + \frac{x_0-x}{x_0-x_3}(H_{f,cupd-1} - H_{f,Cu})$$

---

```

1 x0 = 0.0; x3 = 0.5; x = 0.25;
2 Hf1 = 0.0; Hf3 = -0.12;
3
4 print Hf1 + (x0-x)/(x0-x3)*(Hf3 - Hf1)

```

---

We find the weighted composition formation energy of pure Cu and cupd-1 is more favorable than the formation energy of cu3pd-1. Therefore, we could expect that structure to phase separate into a mixture of pure Cu and cupd-1. Schematically what we are seeing is shown in Figure 8.

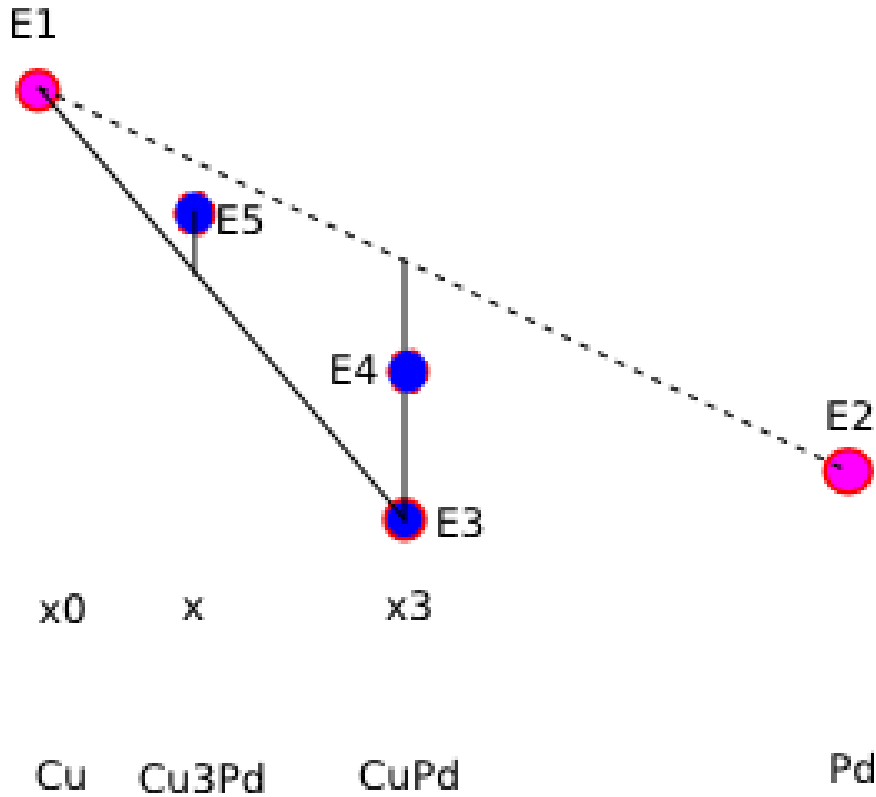

Figure 8: Illustration of phase separation.

Finally, let us consider one more structure with the Cu<sub>3</sub>Pd stoichiometry.

---

```

1 from jasp import *
2 JASPRC['mode']='queue'

```

---

```

3  from ase import Atom, Atoms
4
5  # parent metals
6  with jasp('bulk/alloy/cu') as calc:
7      atoms = calc.get_atoms()
8      cu = atoms.get_potential_energy()/len(atoms)
9
10 with jasp('bulk/alloy/pd') as calc:
11     atoms = calc.get_atoms()
12     pd = atoms.get_potential_energy()/len(atoms)
13
14 atoms = Atoms([Atom('Cu', [-1.867, 1.867, 0.000]),
15               Atom('Cu', [0.000, 0.000, 0.000]),
16               Atom('Cu', [0.000, 1.867, 1.867]),
17               Atom('Pd', [-1.867, 0.000, 1.867]),
18               cell=[[-3.735, 0.000, 0.000],
19                   [0.000, 0.000, 3.735],
20                   [0.000, 3.735, 0.000]])
21
22 with jasp('bulk/alloy/cu3pd-2',
23         xc='PBE',
24         encut=350,
25         kpts=(8,8,8),
26         nbands=34,
27         ibrion=2,
28         isif=4,
29         nsw=10,
30         atoms=atoms) as calc:
31     e4 = atoms.get_potential_energy()
32     for atom in atoms:
33         if atom.symbol == 'Cu':
34             e4 -= cu
35         else:
36             e4 -= pd
37     e4 /= len(atoms)
38 print 'Delta Hf cu3pd-2 = {0:1.2f} eV/atom'.format(e4)

```

---

This looks promising: the formation energy is much more favorable than cu3pd-1, and it is below the composition weighted formation energy of -0.06 eV/atom. Consequently, we conclude that this structure will not phase separate into a mixture of Cu and CuPd. We cannot say, however, if there is a more stable phase, or if it might phase separate into two other phases. We also note here that we have ignored a few other contributions to alloy stability. We have only considered the electronic energy contributions to the formation energy. At temperatures above absolute zero there are additional contributions including configurational and vibrational entropy, which may stabilize some structures more than others. Finally, our analysis is limited to comparisons of the structures computed on the fcc lattice. In fact, it is known that the CuPd alloy forms a bcc structure. We did not calculate that structure, so we can not say if it is more or less stable than the obvious fcc

structure we found.

Figure 9: Illustration of phase separation.

The construction of alloy phase diagrams is difficult. You are always faced with the possibility that there is a phase that you have not calculated that is more stable than the ones you did calculate. One approach is to use a tool that automates the discovery of relevant structures such as the Alloy Theoretic Automated Toolkit (ATAT) [40, 41] which uses a cluster expansion methodology.

#### 4.6.2 Metal oxide oxidation energies

We will consider here the reaction  $2Cu_2O + O_2 \rightleftharpoons 4CuO$ . We need to compute the energy of each species.

## Cu2O calculation

---

```
1 from jasp import *
2
3 from ase.visualize import *
4 from ase import Atom, Atoms
5
6 #http://phycomp.technion.ac.il/~ira/types.html#Cu2O

18
19 atoms = Atoms([Atom('Cu', 0.5*a2),
20                Atom('Cu', 0.5*a1 + 0.5*a3),
21                Atom('O', -y*a1 + y*a2 + 0.25*a3),
```

```

22         Atom('O', y*a1 - y*a2 - 0.25*a3)],
23         cell=(a1, a2, a3))
24
25 with jasp('bulk/CuO',
26           encut=400,
27           kpts=(8,8,8),
28           ibrion=2,
29           isif=3,
30           nsw=30,
31           xc='PBE',
32           atoms=atoms) as calc:
33     calc.set_nbands()
34     print atoms.get_potential_energy()
35     print calc

```

---

## Reaction energy calculation

```

1  from jasp import *
2
3  # don't forget to normalize your total energy to a formula unit. Cu2O has 3 atoms, so the number of formula units in
4  with jasp('bulk/Cu2O') as calc:
5      atoms = calc.get_atoms()
6      cu2o_energy = atoms.get_potential_energy()/(len(atoms)/3)
7
8  with jasp('bulk/CuO') as calc:
9      atoms = calc.get_atoms()
10     cuo_energy = atoms.get_potential_energy()/(len(atoms)/2)
11
12 # make sure to use the same cutoff energy for the O2 molecule!
13 with jasp('molecules/O2-sp-triplet-400') as calc:
14     atoms = calc.get_atoms()
15     o2_energy = atoms.get_potential_energy()
16
17 rxn_energy = 4.0*cuo_energy - o2_energy - 2.0*cu2o_energy
18 print rxn_energy

```

---

There are a few reasons why our number does not agree with the experimental reaction energy. One reason is related to errors in the O<sub>2</sub> dissociation energy, and another reason is related to localization of electrons in the Cu 3d orbitals [43]. The first error of incorrect O<sub>2</sub> dissociation error is a systematic error that can be corrected empirically [43]. Fixing the second error requires the application of DFT+U.

## 4.7 Bulk density of states

```

1  from ase import Atoms, Atom
2  from jasp import *
3  import sys
4

```

```

5  from pylab import *
6  import numpy as np
7  from ase.dft import DOS
8
9  a = 3.9 # approximate lattice constant
10 b = a / 2.
11 bulk = Atoms([Atom('Pd', (0.0, 0.0, 0.0))],
12              cell=[(0, b, b),
13                    (b, 0, b),
14                    (b, b, 0)])
15
16 with jasp('bulk/pd-dos',
17          encut=300,
18          xc='PBE',
19          lreal=False,
20          kpts=(8, 8, 8), # this is too low for high quality DOS
21          atoms=bulk) as calc:
22
23     # this runs the calculation
24     bulk.get_potential_energy()
25     dos = DOS(calc, width=0.2)
26     d = dos.get_dos()
27     e = dos.get_energies()
28
29 import pylab as plt
30 plt.plot(e,d)
31 plt.xlabel('energy [eV]')
32 plt.ylabel('DOS')
33 plt.savefig('images/pd-dos.png')

```

---

This DOS looks roughly like you would expect. The peak between -5 to 0 eV is the Pd d-band.

The vasp manual [recommends](#) a final run be made with ISMEAR=-5, which uses the tetrahedron method with Blochl corrections.

---

```
1 from jasp import *
2 from ase.dft import DOS
3 with jasp('bulk/pd-dos') as calc:
4     calc.clone('bulk/pd-dos-ismear-5')
5
6 with jasp('bulk/pd-dos-ismear-5') as calc:
7     bulk = calc.get_atoms()
8
9     calc.set(ismear=-5)
10
11     bulk.get_potential_energy()
12     dos = DOS(calc, width=0.2)
13     d = dos.get_dos()
14     e = dos.get_energies()
15
16 import pylab as plt
17 plt.plot(e, d)
18 plt.xlabel('energy [eV]')
19 plt.ylabel('DOS')
20 plt.savefig('images/pd-dos-ismear-5.png')
```

---

This is not that different from the regular ISMEAR, so I am not sure this is cor-

rect. Maybe there is another way to compute DOS when the tetrahedral method is used? This looks like the eigenvalue spectrum.

## 4.8 Atom projected density of states

In this example, we consider how to get the atom-projected density of states. We are interested in properties of the *d*-band on Pd, such as the *d*-band center and *d*-band width.

---

```
1 from ase import Atoms, Atom
2 from jasp import *
3 from ase.calculators.vasp import VaspDos
4 import sys
5
6 from pylab import *
7 import numpy as np
8
9 a = 3.9 # approximate lattice constant
10 b = a / 2.
11 bulk = Atoms([Atom('Pd', (0.0, 0.0, 0.0))],
12             cell=[(0, b, b),
13                  (b, 0, b),
14                  (b, b, 0)])
15
16 with jasp('bulk/pd-ados',
17          encut=300,
18          xc='PBE',
19          lreal=False,
20          rwigs=[1.5], # wigner-seitz radii for ados
21          kpts=(8, 8, 8),
22          atoms=bulk) as calc:
23
24     # this runs the calculation
25     bulk.get_potential_energy()
26
27     # now get results
28     ados = VaspDos(efermi=calc.get_fermi_level())
29
30     energies = ados.energy
31     dos = ados.site_dos(0, 'd')
32
33     #we will select energies in the range of -10, 5
34     ind = (energies < 5) & (energies > -10)
35
36     energies = energies[ind]
37     dos = dos[ind]
38
39     Nstates = np.trapz(dos, energies)
40     occupied = energies <= 0.0
41     N_occupied_states = np.trapz(dos[occupied], energies[occupied])
42     ed = np.trapz(energies * dos, energies) / np.trapz(dos, energies)
43     wd2 = np.trapz(energies**2 * dos, energies) / np.trapz(dos, energies)
44
```

```

45     print 'Total # states = %1.2f' % Nstates
46     print 'number of occupied states = %1.2f' % N_occupied_states
47     print 'd-band center = %1.2f eV' % ed
48     print 'd-band width = %1.2f eV' % np.sqrt(wd2)
49
50     # plot the d-band
51     plot(energies, dos, label='$d$-orbitals')
52
53     # plot the occupied states in shaded gray
54     fill_between(x=energies[occupied],
55                 y1=dos[occupied],
56                 y2=zeros(dos[occupied].shape),
57                 color='gray')
58
59     xlabel('$E - E_f$ (eV)')
60     ylabel('DOS (arbitrary units)')
61
62     savefig('images/pd-ados.png')

```

---

## 4.9 Band structures

To compute a band structure we do two things. First, we compute the self-consistent band structure. Then we compute the band structure at the desired k-points. We will use Si as an example (adapted from <http://bbs.sciencenet.cn/bbs/upload/20083418325986.pdf>)

---

```

1  from jasp import *
2  JASPRC['queue.walltime'] = '10:00:00'
3
4  from ase import Atom, Atoms
5  from ase.visualize import view
6
7  a = 5.38936
8  atoms = Atoms([Atom('Si',[0,0,0]),
9                 Atom('Si',[0.25, 0.25, 0.25])])
10
11 atoms.set_cell([[a/2., a/2., 0.0],
12               [0.0, a/2., a/2.],
13               [a/2., 0.0, a/2.]],scale_atoms=True)
14
15 with jasp('bulk/Si-selfconsistent',
16          xc='PBE',
17          prec='Medium',
18          istsart=0,
19          icharg=2,
20          ediff=0.1e-03,
21          kpts=(4,4,4),
22          atoms=atoms) as calc:
23      print atoms.get_potential_energy()

```

---

Now, we run a new calculation along the k-point path desired. The standard VASP way of doing this is to modify the INCAR and KPOINTS file and rerun VASP. We will not do that. Doing that results in some lost information if you overwrite the old files. We will copy the old directory to a new directory, using code to ensure this only happens one time.

---

```

1  from jasp import *
2  JASPRC['queue.walltime'] = '10:00:00'
3
4  import os, shutil
5
6  wd = 'bulk/Si-bandstructure'
7
8  if not os.path.isdir(wd):
9      shutil.copytree('bulk/Si-selfconsistent', wd)
10
11 kpts = [[0.5,0.5,0.0], # L
12         [0,0,0],      # Gamma
13         [0,0,0],
14         [0.5, 0.5, 0.5]] # X
15
16 with jasp(wd) as calc:
17     calc.set(icharg=11) # update incar
18     calc.write_kpoints(mode='line',
19                       kpts=kpts,
20                       kpt_format='rec',
21                       intersections=10) # make new kpoint file
22     print calc.calculate()

```

23

24 *# note you cannot run this script more than once because vasp.py does not know how to read in our new kpoint file yet*

`:func:ase.calculators.vasp.Vasp.read_kpoints` does not support reading in this KPOINTS file yet. jasp does not have a fancy way of extracting band structures yet, so we will learn how to manually parse the EIGENVAL file here to generate the band structure.

---

```

1  f = open('bulk/Si-bandstructure/EIGENVAL', 'r')
2
3  line1 = f.readline()
4  line2 = f.readline()
5  line3 = f.readline()
6  line4 = f.readline()
7  comment = f.readline()
8  unknown, npoints, nbands = [int(x) for x in f.readline().split()]
9
10 blankline = f.readline()
11
12 band_energies = [[] for i in range(nbands)]
13
14 for i in range(npoints):
15     x,y,z, weight = [float(x) for x in f.readline().split()]
16
17     for j in range(nbands):
18         fields = f.readline().split()
19         id, energy = int(fields[0]), float(fields[1])
20         band_energies[id-1].append(energy)
21     blankline = f.readline()
22 f.close()
23
24 import matplotlib.pyplot as plt
25
26 for i in range(nbands):
27     plt.plot(range(npoints), band_energies[i])
28
29 ax = plt.gca()
30 ax.set_xticks([]) # no tick marks
31 plt.xlabel('k-vector')
32 ax.set_xticks([0,10,19])
33 ax.set_xticklabels(['$L$', '$\Gamma$', '$X$'])
34 plt.savefig('bulk/Si-bandstructure/bandstructure.png')

```

---

## 4.10 Simulated XRD spectra

You do not really need a DFT calculation for this, except to get the optimized structure. A few notes on using this module:

1. You need a large repeat unit cell.
2. It is not fast. There is a double loop over the atoms, meaning  $N^2$  operations, and you need large unit cells!
3. This example is primarily a proof of concept. I have not thought about how good the results are.

---

```

1  from ase import Atom, Atoms
2  from ase.xrdebye import *
3  import numpy as np
4
5  wavelength = 1.051967 # in angstroms
6
7  XRD = XrDebye(wavelength=wavelength, alpha=1.01, damping=0.0)
8
9  a = 3.92 # approximate lattice constant
10 b = a / 2.
11 atoms = Atoms([Atom('Pd', (0.0, 0.0, 0.0))],
12               cell=[(0, b, b),

```

```

13         (b, 0, b),
14         (b, b, 0)]).repeat((5,5,5))
15
16 thetas = np.linspace(0.2, np.pi/4.)
17
18 I = [XRD.get(atoms,s=s) for s in 2*np.sin(thetas)/wavelength]
19
20 import matplotlib.pyplot as plt
21 plt.plot((2*thetas)*180./np.pi,I)
22 plt.xlabel('$2\Theta$')
23 plt.ylabel('Intensity (arb. units)')
24 plt.savefig('images/pd-xrd.png')

```

---

## 4.11 Magnetism

### 4.11.1 Determining if a magnetic solution is energetically favorable

We can force a total magnetic moment onto a unit cell and compute the total energy as function of the total magnetic moment. If there is a minimum in the energy, then we know there is a lower energy magnetic solution than a non-magnetic solution.

---

```

1 from jasp import *
2 JASPRC['queue.walltime'] = '1:00:00'

```

```

3  from ase.lattice.cubic import BodyCenteredCubic
4
5  atoms = BodyCenteredCubic(directions=[[1,0,0],
6                                         [0,1,0],
7                                         [0,0,1]],
8                               size=(1,1,1),
9                               symbol='Fe')
10
11  NUPDOWNS = [0.0, 2.0, 4.0, 5.0, 6.0, 8.0]
12  energies = []
13  for B in NUPDOWNS:
14      with jasp('bulk/Fe-bcc-fixedmagmom-{:1.2f}'.format(B),
15                xc='PBE',
16                encut=300,
17                kpts=(4,4,4),
18                ispin=2,
19                nupdown=B,
20                atoms=atoms) as calc:
21          try:
22              e = atoms.get_potential_energy()
23              energies.append(e)
24          except (VaspSubmitted, VaspQueued):
25              pass
26
27  import matplotlib.pyplot as plt
28  plt.plot(NUPDOWNS, energies)
29  plt.xlabel('Total Magnetic Moment')
30  plt.ylabel('Energy (eV)')
31  plt.savefig('images/Fe-fixedmagmom.png')

```

---

You can see here there is a minimum in energy at a total magnetic moment somewhere between 4 and 5. There are two Fe atoms in the unit cell, which means the magnetic moment on each atom must be about 2.5 Bohr-Magnetons. This is a good guess for a real calculation. Note that Vasp [recommends](#) you overestimate the magnetic moment guesses if you are looking for ferromagnetic solutions.

---

```

1 from jasp import *
2 JASPRC['queue.walltime'] = '1:00:00'
3 from ase.lattice.cubic import BodyCenteredCubic
4
5
6 atoms = BodyCenteredCubic(directions=[[1,0,0],
7                                       [0,1,0],
8                                       [0,0,1]],
9                             size=(1,1,1),
10                            symbol='Fe')
11
12 for atom in atoms:
13     atom.magmom = 2.5
14
15 with jasp('bulk/Fe-bcc-sp-1',
16          xc='PBE',
17          encut=300,
18          kpts=(4,4,4),
19          ispin=2,
20          atoms=atoms) as calc:
21     try:
22         e = atoms.get_potential_energy()
23         print atoms.get_magnetic_moment()
24         print atoms.get_magnetic_moments()
25     except (VaspSubmitted, VaspQueued):
26         pass

```

---

#### 4.11.2 Antiferromagnetic spin states

---

```

1 from jasp import *
2 from ase import Atom, Atoms
3
4 atoms = Atoms([Atom('Fe', [0.00, 0.00, 0.00], magmom=5),
5               Atom('Fe', [4.3, 4.3, 4.3], magmom=-5),
6               Atom('O', [2.15, 2.15, 2.15], magmom=0),
7               Atom('O', [6.45, 6.45, 6.45], magmom=0)],
8              cell=[[4.3, 2.15, 2.15],
9                  [2.15, 4.3, 2.15],
10                 [2.15, 2.15, 4.3]])
11
12 with jasp('bulk/afm-feo',
13          encut=350,
14          prec='Normal',
15          ispin=2,

```

```

16         nupdown=0, # this forces a non-magnetic solution
17         lorbit=11,
18         lreal=False,
19         atoms=atoms) as calc:
20     print atoms.get_magnetic_moments()
21     print atoms.get_magnetic_moment()

```

---

```

[ 2.652 -2.652  0.    0.   ]
0.0

```

You can see that even though the total magnetic moment is 0, there is a spin on both Fe atoms, and they are pointing in opposite directions.

### 4.11.3 TODO NiO-FeO formation energies with magnetism

### 4.12 TODO phonons

## 5 Surfaces

### 5.1 Surface structures

#### 5.1.1 Simple surfaces

ase provides many [utility functions](#) to setup surfaces. Here is a simple example of an fcc111 Al surface. There are built in functions for fcc111, bcc110, bcc111, hcp001 and diamond111.

---

```

1 from ase.lattice.surface import *
2 from ase.io import write
3
4 slab = fcc111('Al', size=(2,2,3), vacuum=10.0)
5
6 write('images/Al-slab.png', slab, rotation='90x', show_unit_cell=2)

```

---

### 5.1.2 vicinal surfaces

Many stepped surfaces are not that difficult to make now. The main idea in generating them is described [here](#). ase provides a general function for making vicinal surfaces. Here is an example.

---

```
1 from ase.lattice.surface import surface
2 from ase.io import write
3
4 # Au(211) with 9 layers
5 s1 = surface('Au', (2, 1, 1), 9)
6 s1.center(vacuum=10, axis=2)
7
8 write('images/Au-211.png',
9       s1.repeat((3,3,1)),
10      rotation='-30z,90x', # change the orientation for viewing
11      show_unit_cell=2)
```

---

## 5.2 Surface relaxation

When a surface is created, the bulk symmetry is broken and consequently there will be forces on the surface atoms. We will examine some consequences of this with a simple Al slab. First, we show there are forces on the slab atoms.

---

```

1 from jasp import *
2 from ase.lattice.surface import *
3
4 atoms = fcc111('Al', size=(1,1,4), vacuum=10.0)
5
```

---

```

6 with jasp('surfaces/Al-slab-unrelaxed',
7         xc='PBE',
8         kpts=(6,6,1),
9         encut=350,
10        atoms=atoms) as calc:
11     atoms.get_forces()
12     print calc

```

---

Some points to note. The forces on the atoms have symmetry to them.

---

```

1 from jasp import *
2 from ase.lattice.surface import *
3
4 atoms = fcc111('Al', size=(1,1,4), vacuum=10.0)
5
6 with jasp('surfaces/Al-slab-unrelaxed') as calc:
7     atoms = calc.get_atoms()
8
9     for i in range(1,len(atoms)):
10         print atoms[i].z - atoms[i-1].z

```

---

We have to make some decisions about how to relax the slab. One choice would be to relax all the atoms in the slab. If we do that, then there will be no atoms with bulk like spacing unless we increase the slab thickness pretty dramatically. It is pretty common to freeze some atoms at the bulk coordinates, and let the others relax. We will freeze the bottom two layers (defined by tags 3 and 4) and let the first two layers relax. To do that we add constraints to the slab.

Note: the [ase constraints](#) are only partially used by jasp/vasp. The FixAtoms constraint gets written to the POSCAR file, and is then used internally in Vasp. The only other constraint that Vasp can use internally is FixScaled. The other constraints are not written to the POSCAR and are not used by Vasp.

TODO: show how to use other ase.constraints with jasp.

---

```

1 from jasp import *
2 from ase.lattice.surface import *
3 from ase.constraints import FixAtoms
4
5 atoms = fcc111('Al', size=(1,1,4), vacuum=10.0)
6
7 with jasp('surfaces/Al-slab-relaxed',
8         xc='PBE',
9         kpts=(6,6,1),
10        encut=350,
11        ibrion=2,
12        isif=2,

```

---

```

13         nsw=10,
14         atoms=atoms) as calc:
15
16     constraint = FixAtoms(mask=[atom.tag >= 3 for atom in atoms])
17     atoms.set_constraint(constraint)
18
19     atoms.get_forces()
20     print calc

```

---

You can see that atoms 2 and 3 (the ones we relaxed) now have very low forces on them and it appears that atoms 0 and 1 have no forces on them. That is because the FixAtoms constraint works by setting the forces on those atoms to zero. We can see in the next example that the z-positions of the relaxed atoms have indeed relaxed and changed, while the position of the frozen atoms did not change.

---

```

1  from jasp import *
2  from ase.lattice.surface import *
3
4  atoms = fcc111('Al', size=(1,1,4), vacuum=10.0)
5
6  with jasp('surfaces/Al-slab-relaxed') as calc:
7      atoms = calc.get_atoms()
8
9      for i in range(1,len(atoms)):
10         print 'd_({0},{1}) = {2}'.format(i,i-1,
11                                           atoms[i].z - atoms[i-1].z)

```

---

### 5.2.1 TODO Surface reconstruction

maybe a 110 missing row reconstruction? [6]

## 5.3 Work function

To get the work function, we need to have the local potential. this is not written by default in vasp, and we have to tell it to do that with the LVTOT keyword.

---

```

1  from jasp import *
2  from ase.lattice.surface import *
3  from ase.constraints import FixAtoms
4  from pylab import *
5  from jasp.volumetric_data import *
6
7  with jasp('surfaces/Al-slab-relaxed') as calc:
8      atoms = calc.get_atoms()
9

```

---

```

10 with jasp('surfaces/Al-slab-locpot',
11           xc='PBE',
12           kpts=(6,6,1),
13           encut=350,
14           lvtot=True, # write out local potential
15           lvhar=True, # write out only electrostatic potential, not xc pot
16           atoms=atoms) as calc:
17
18     calc.calculate()
19     ef = calc.get_fermi_level()
20
21     atoms = calc.get_atoms()
22
23     x,y,z,lp = calc.get_local_potential()
24
25     nx, ny, nz = lp.shape
26
27     axy = np.array([np.average(lp[:, :, z]) for z in range(nz)])
28     # setup the x-axis in realspace
29     uc = atoms.get_cell()
30     xaxis = np.linspace(0, uc[2][2], nz)
31
32     plot(xaxis, axy)
33     plot([min(xaxis), max(xaxis)], [ef, ef], 'k:')
34     savefig('images/Al-wf.png')
35
36     ind = (xaxis > 0) & (xaxis < 5)
37     wf = np.average(axy[ind]) - ef
38     print ' The workfunction is {0:1.2f} eV'.format(wf)

```

---

The workfunction of Al is listed as 4.08 at <http://hyperphysics.phy-astr.gsu.edu/hbase/tables/photoelec.html>.

## 5.4 Surface energy

The easiest way to calculate surface energies is from this equation:

$$\sigma = \frac{1}{2} \left( E_{slab} - \frac{N_{slab}}{N_{bulk}} E_{bulk} \right)$$

where  $E_{slab}$  is the total energy of a symmetric slab (i.e. one with inversion symmetry, and where both sides of the slab have been relaxed),  $E_{bulk}$  is the total energy of a bulk unit cell,  $N_{slab}$  is the number of atoms in the slab, and  $N_{bulk}$  is the number of atoms in the bulk unit cell. One should be sure that the bulk energy is fully converged with respect to  $k$ -points, and that the slab energy is also converged with respect to  $k$ -points. The energies should be compared at the same cutoff energies. The idea is then to increase the thickness of the slab until the surface energy  $\sigma$  converges.

Unfortunately, this approach does not always work. The bulk system is treated subtly different than the slab system, particularly in the  $z$ -direction where the vacuum is (where typically only one  $k$ -point is used in slabs). Consequently, the  $k$ -point sampling is not equivalent in the two systems, and one can in general expect some errors due to this, with the best case being cancellation of the errors due to total  $k$ -point convergence. In the worst case, one can get a linear divergence in the surface energy with slab thickness [4].

A variation of this method that usually results in better  $k$ -point error

Figure 10: Schematic figure illustrating the calculation of a surface energy.

cancellation is to calculate the bulk unit cell energy using the slab unit cell with no vacuum space, with the same  $k$ -point mesh in the  $x$  and  $y$  directions, but with increased  $k$ -points in the  $z$ -direction. Thus, the bulk system and slab system have the same Brillouin zone in at least two dimensions. This maximizes the cancellation of  $k$ -point errors, but still does not guarantee convergence of the surface energy, as discussed in [4, 5].

For quick estimates of the surface energy, one of the methods described above is likely sufficient. The advantage of these methods is the small number of calculations required to obtain the estimate, one needs only a bulk calculation (which must be done anyhow to get the bulk lattice constant to create the slab), and a slab calculation that is sufficiently thick to get the estimate. Additional calculations are only required to test the convergence of the surface energy.

An alternative method for calculating surface energies that does not involve an explicit bulk calculation follows Ref. [5]. The method follows from equation (ref{eq:se}) where for a  $N$ -atom slab, in the limit of  $N \rightarrow \infty$ ,

$$E_{slab} \approx 2\sigma + \frac{N_{slab}}{N_{bulk}} E_{bulk}$$

Then, we can estimate  $E_{bulk}$  by plotting the total energy of the slab as a function of the slab thickness.

$$\sigma = \lim_{N \rightarrow \infty} \frac{1}{2} (E_{slab}^N - N \Delta E_N)$$

where  $\Delta E_N = E_{slab}^N - E_{slab}^{N-1}$ .

We will examine this approach here. We will use unrelaxed slabs for computational efficiency.

---

```
1 from jasp import *
2 from ase.units import *
3 from ase.lattice.surface import *
4 import matplotlib.pyplot as plt
5
6 Nlayers = [3, 4, 5, 6, 7, 8, 9, 10, 11]
7 energies = []
8 sigmas = []
9
10 for n in Nlayers:
11
12     slab = fcc111('Cu', size=(1,1,n), vacuum=10.0)
13     slab.center()
14
15     with jasp('bulk/Cu-layers/{0}'.format(n),
16              xc='PBE',
17              encut=350,
18              kpts=(8,8,1),
19              atoms=slab) as calc:
20         calc.set_nbands(f=2) # the default nbands in Vasp is too low for Al
21         try:
22             energies.append(slab.get_potential_energy())
23         except (VaspSubmitted, VaspQueued):
24             pass
25
26 for i in range(len(Nlayers)-1):

31     print 'sigma = {0} eV/atom'.format(sigma)
32
33 plt.plot(Nlayers[0:-1], sigmas,'bo-')
34 plt.xlabel('Number of layers')
35 plt.ylabel('Surface energy (eV/atom)')
36 plt.savefig('images/Cu-unrelaxed-surface-energy.png')
```

---

One

reason for the oscillations may be quantum size effects [8]. In [39] the surface energy of Cu(111) is reported as 0.48 eV/atom, or 1.36 J/m<sup>2</sup>. Here is an example showing a conversion between these two units. We use ase to compute the area of the unit cell from the norm of the cross-product of the vectors defining the surface unit cell.

---

```

1 from ase.lattice.surface import *
2 from ase.units import *
3 import numpy as np
4
5 slab = fcc111('Cu', size=(1,1,3), vacuum=10.0)
6 cell = slab.get_cell()
7
8 area = np.linalg.norm(np.cross(cell[0], cell[1]))
9
10 sigma = 0.48 #eV/atom
11
12 print 'sigma = {0} J/m^2'.format(sigma/area/(J/m**2))

```

---

#### 5.4.1 Advanced topics in surface energy

The surface energies can be used to estimate the shapes of nanoparticles using a Wulff construction. See [10] for an example of computing Mo<sub>2</sub>C surface energies and particle shapes, and [44] for an example of the influence of adsorbates on surface energies and particle shapes of Cu.

For a classic paper on trends in surface energies see [42] .

## 5.5 Dipole correction

Slabs that are not symmetric (e.g. they have adsorbates on only one side) can develop dipole moments. Periodic dipoles can be problematic, as they create an artificial field that may affect the surface properties such as the work function and the convergence of the calculations. The solution to this problem is to introduce a dipole field in the cell to exactly cancel the dipole moment [35] (see [2] for a small correction) to minimize the effect.

Here we will just illustrate the effect.

### 5.5.1 slab with no dipole correction

---

```
1  #!/usr/bin/env python
2  from ase.lattice.surface import *
3  from jasp import *
4  from jasp.volumetric_data import *
5
6  slab = fcc111('Al', size=(2,2,2), vacuum=10.0)
7  add_adsorbate(slab, 'Na', height=1.2, position='fcc')
8
9  slab.center()
10
11 with jasp('surfaces/Al-Na-nodip',
12          xc='PBE',
13          encut=340,
14          kpts=(2,2,1),
15          lvtot=True, # write out local potential
16          lvhar=True, # write out only electrostatic potential, not xc pot
17          atoms=slab) as calc:
18      calc.calculate()
19
20      x,y,z,lp = calc.get_local_potential()
21      nx, ny, nz = lp.shape
22
23      axy = [np.average(lp[:, :, z]) for z in range(nz)]
24      # setup the x-axis in realspace
25      uc = atoms.get_cell()
26      xaxis = np.linspace(0, uc[2][2], nz)
27
28      plot(xaxis, axy)
29      show()
```

---

### 5.5.2 slab with a dipole correction

Note this takes a considerably longer time to run than without a dipole correction! In Vasp there are several levels of dipole correction to apply.

You can use the IDIPOL tag to turn it on, and specify which direction to apply it in (1=x, 2=y, 3=z, 4=all directions). This simply corrects the total energy and forces. It does not change the contents of LOCPOT. For that, you have to also set the LDIPOL and DIPOL tags. It is not efficient to set all three at the same time for some reason. The Vasp manual recommends you first set IDIPOL to get a converged electronic structure, and then set LDIPOL to True, and set the center of electron density in DIPOL. That makes these calculations a multistep process, because we must run a calculation, analyze the charge density to get the center of charge, and then run a second calculation.

---

```

1  from ase.lattice.surface import *
2  from jasp import *
3  JASPRC['mode'] = 'run'
4  slab = fcc111('Al', size=(2,2,2), vacuum=10.0)
5  add_adsorbate(slab, 'Na', height=1.2, position='fcc')
6
7  slab.center()
8
9  with jasp('surfaces/Al-Na-dip',
10          xc='PBE',
11          encut=340,
12          kpts=(2,2,1),
13          idipol=3, # only along z-axis
14          lvtot=True, # write out local potential
15          lvhar=True, # write out only electrostatic potential, not xc pot
16          atoms=slab) as calc:
17      # pre-converge
18      calc.calculate()
19
20      x,y,z,cd = calc.get_charge_density()
21      n0, n1, n2 = cd.shape
22      nelements = n0*n1*n2
23      voxel_volume = slab.get_volume()/nelements
24      total_electron_charge = cd.sum()*voxel_volume
25
26      electron_density_center = np.array([(cd*x).sum(),
27                                         (cd*y).sum(),
28                                         (cd*z).sum()])
29
30      electron_density_center *= voxel_volume
31      electron_density_center /= total_electron_charge
32
33      print electron_density_center
34      uc = slab.get_cell()
35
36      # get scaled electron charge density center
37      sedc = np.dot(np.linalg.inv(uc.T), electron_density_center.T).T
38
39      ## # now turn on potential calculation: violates jasp workflow!
40      calc.set(ldipol=True, dipol=sedc)
41
42      calc.calculate()

```

---

### 5.5.3 Comparing no dipole correction with a dipole correction

To see the difference in what the dipole correction does, we now plot the potentials from each calculation.

---

```
1 from jasp import *
2 from pylab import *
3
4 with jasp('surfaces/Al-Na-nodip') as calc:
5     atoms = calc.get_atoms()
6
7     x,y,z,lp = calc.get_local_potential()
8     nx, ny, nz = lp.shape
9
10    axy_1 = [np.average(lp[:, :, z]) for z in range(nz)]
11    # setup the x-axis in realspace
12    uc = atoms.get_cell()
13    xaxis_1 = np.linspace(0, uc[2][2], nz)
14
15    e1 = atoms.get_potential_energy()
16
17 with jasp('surfaces/Al-Na-dip') as calc:
18     atoms = calc.get_atoms()
19
20     x,y,z,lp = calc.get_local_potential()
21     nx, ny, nz = lp.shape
22
23    axy_2 = [np.average(lp[:, :, z]) for z in range(nz)]
24    # setup the x-axis in realspace
25    uc = atoms.get_cell()
26    xaxis_2 = np.linspace(0, uc[2][2], nz)
27
28    ef2 = calc.get_fermi_level()
29    e2 = atoms.get_potential_energy()
30
31 print 'The difference in energy is {0} eV.'.format(e2-e1)
32
33 plot(xaxis_1, axy_1, label='no dipole correction')
34 plot(xaxis_2, axy_2, label='dipole correction')
35 plot([min(xaxis_2), max(xaxis_2)], [ef2, ef2], 'k:', label='Fermi level')
36 xlabel('z ($\AA$)')
37 ylabel('xy-averaged electrostatic potential')
38 legend(loc='best')
39 savefig('images/dip-vs-nodip-esp.png')
```

---

The key points to notice in this figure are:

1. The two deep dips are where the atoms are.

2. Without a dipole correction, the electrostatic potential never flattens out. there is near constant slope in the vacuum region, which means there is an electric field there.
3. With a dipole moment the potential is flat in the vacuum region, except for the step jump near 23 Å.
4. The difference between the Fermi level and the flat vacuum potential is the work function.
5. The difference in energy with and without the dipole correction here is small.

## 5.6 Adsorption energies

### 5.6.1 simple estimate

Calculating an adsorption energy amounts to computing the energy of the following kind of reaction:

There are many variations of this idea. The slab may already have some adsorbates on it, the slab may reconstruct on adsorption, the gas-phase molecule may or may not dissociate, and the products may or may not stick

to the surface. We have to decide where to put the adsorbates, i.e. what site to put them on, and some sites will be more stable than others. We will consider the dissociative adsorption of O<sub>2</sub> on three sites of a Pt(111) slab. We will assume the oxygen molecule has split in half, and that the atoms have moved far apart. We will model the oxygen coverage at 0.25 ML, which means we need to use a 2 × 2 surface unit cell. For computational speed, we will freeze the slab, but allow the adsorbate to relax.

$$\Delta H_{ads}(eV/O) = E_{slab+O} - E_{slab} - 0.5 * E_{O_2}$$

## Calculations

### clean slab calculation

---

```

1 from jasp import *
2 from ase.lattice.surface import *
3 from ase.constraints import FixAtoms
4
5 atoms = fcc111('Pt', size=(2,2,3), vacuum=10.0)

```

1  from jasp import *
2  from ase.lattice.surface import *
3  from ase.constraints import FixAtoms
4
5  atoms = fcc111('Pt', size=(2,2,3), vacuum=10.0)
6
7  # note this function only works when atoms are created by the surface module.
8  add_adsorbate(atoms, 'O', height=1.2, position='hcp')
9
10 constraint = FixAtoms(mask=[atom.symbol != 'O' for atom in atoms])
11 atoms.set_constraint(constraint)
12
13 with jasp('surfaces/Pt-slab-0-hcp',
14         xc='PBE',
15         kpts=(4,4,1),
16         encut=350,
17         ibrion=2,
18         nsw=25,
19         atoms=atoms) as calc:
20     print atoms.get_potential_energy()

```

---

## Analysis of adsorption energies

---

```
1 from jasp import *
2 from ase.io import write
3
4 with jasp('surfaces/Pt-slab') as calc:
5     atoms = calc.get_atoms()
6     e_slab = atoms.get_potential_energy()
7     write('images/pt-slab.png', atoms, show_unit_cell=2)
8
9 with jasp('surfaces/Pt-slab-0-fcc') as calc:
10     atoms = calc.get_atoms()
11     e_slab_o_fcc = atoms.get_potential_energy()
12     write('images/pt-slab-fcc-o.png', atoms, show_unit_cell=2)
13
14 with jasp('surfaces/Pt-slab-0-hcp') as calc:
15     atoms = calc.get_atoms()
16     e_slab_o_hcp = atoms.get_potential_energy()
17     write('images/pt-slab-hcp-o.png', atoms, show_unit_cell=2)
18
19 with jasp('surfaces/Pt-slab-0-bridge') as calc:
20     atoms = calc.get_atoms()
21     e_slab_o_bridge = atoms.get_potential_energy()
22     write('images/pt-slab-bridge-o.png', atoms, show_unit_cell=2)
23
24 with jasp('molecules/O2-sp-triplet-350') as calc:
25     atoms = calc.get_atoms()
26     e_O2 = atoms.get_potential_energy()
27
28 Hads_fcc = e_slab_o_fcc - e_slab - 0.5*e_O2
29 Hads_hcp = e_slab_o_hcp - e_slab - 0.5*e_O2
30 Hads_bridge = e_slab_o_bridge - e_slab - 0.5*e_O2
31
32 print 'Hads (fcc) = {0} eV/0'.format(Hads_fcc)
33 print 'Hads (hcp) = {0} eV/0'.format(Hads_hcp)
34 print 'Hads (bridge) = {0} eV/0'.format(Hads_bridge)
```

---

You can see the hcp site is not as energetically favorable as the fcc site. Interestingly, the bridge site seems to be as favorable as the fcc site. This is not correct, and to see why, we have to look at the final geometries of each calculation.

Let us see what the original geometry and final geometry were. The POSCAR contains the initial geometry (as long as you haven't copied CONTCAR to POSCAR), and the CONTCAR contains the final geometry.

---

```
1 from ase.io import read, write
2
3 atoms = read('surfaces/Pt-slab-0-bridge/POSCAR')
4 write('images/Pt-o-brige-ori.png', atoms, show_unit_cell=2)
5
6 atoms = read('surfaces/Pt-slab-0-bridge/CONTCAR')
7 write('images/Pt-o-brige-final.png', atoms, show_unit_cell=2)
```

---

Final geometry

Figure 12: Final geometry of the hcp site.

You can see the problem. We should not call the adsorption energy from this calculation a bridge site adsorption energy because the O atom is actually in an fcc site! This kind of result can happen with relaxation, and you should always check that the result you get makes sense. Next, we consider how to get a bridge site adsorption energy by using constraints.

Some final notes:

1. We did not let the slabs relax in these examples, and allowing them to relax is likely to have a big effect on the adsorption energies. You have to decide how many layers to relax, and check for convergence with respect to the number of layers.
2. The slabs were pretty thin. It is typical these days to see slabs that are 4-5 or more layers thick.
3. We did not consider how well converged the calculations were with respect to k-points or ENCUT.
4. We did not consider the effect of the error in O<sub>2</sub> dissociation energy on the adsorption energies.
5. We did not consider coverage effects.

Figure 13: Final geometry of the bridge site. You can see that the Oxygen atom ended up in the fcc site.

**Adsorption on bridge site with constraints** To prevent the oxygen atom from sliding down into the fcc site, we have to constrain it so that it only moves in the z-direction. This is an artificial constraint; the bridge site is only metastable. But there are lots of reasons you might want to do this anyway. One is the bridge site is a transition state for diffusion between the fcc and hcp sites. Another is to understand the role of coordination in the adsorption energies. We use a `FixScaled` constraint in ase to constrain the O atom so it can only move in the z-direction (actually so it can only move in the direction of the third unit cell vector, which only has a z-component).

---

```

1 from jasp import *
2 JASPRC['mode'] = None
3 from ase.lattice.surface import *
4 from ase.constraints import FixAtoms, FixScaled
5 from ase.io import write
6
7 atoms = fcc111('Pt', size=(2,2,3), vacuum=10.0)
8
9 # note this function only works when atoms are created by the surface module.
10 add_adsorbate(atoms, 'O', height=1.2, position='bridge')
11 constraint1 = FixAtoms(mask=[atom.symbol != 'O' for atom in atoms])
12 # fix in xy-direction, free in z. actually, freeze movement in surface

```

```

13 # unit cell, and free along 3rd lattice vector
14 constraint2 = FixScaled(atoms.get_cell(), 12, [True, True, False])
15
16 atoms.set_constraint([constraint1, constraint2])
17 write('images/Pt-O-bridge-constrained-initial.png', atoms, show_unit_cell=2)
18 print 'Initial O position: {0}'.format(atoms.positions[-1])
19
20 with jasp('surfaces/Pt-slab-O-bridge-xy-constrained',
21          xc='PBE',
22          kpts=(4,4,1),
23          encut=350,
24          ibrion=2,
25          nsw=25,
26          atoms=atoms) as calc:
27     e_bridge = atoms.get_potential_energy()
28
29 write('images/Pt-O-bridge-constrained-final.png', atoms, show_unit_cell=2)
30 print 'Final O position : {0}'.format(atoms.positions[-1])
31
32 # now compute Hads
33 with jasp('surfaces/Pt-slab') as calc:
34     atoms = calc.get_atoms()
35     e_slab = atoms.get_potential_energy()
36
37
38 with jasp('molecules/O2-sp-triplet-350') as calc:
39     atoms = calc.get_atoms()
40     e_O2 = atoms.get_potential_energy()
41
42 Hads_bridge = e_bridge - e_slab - 0.5*e_O2
43
44 print 'Hads (bridge) = {0:1.3f} eV/O'.format(Hads_bridge)

```

---

You can see that only the z-position of the O atom changed. Also, the adsorption energy of O on the bridge site is **much** less favorable than on the fcc or hcp sites.

### 5.6.2 Coverage dependence

The adsorbates on the surface can interact with each other which results in coverage dependent adsorption energies [15]. Coverage dependence is not difficult to model; we simply compute adsorption energies in different size unit cells, and/or with different adsorbate configurations. Here we consider dissociative oxygen adsorption at 1ML on Pt(111) in an fcc site, which is one oxygen atom in a  $1 \times 1$  unit cell.

For additional reading, see these references from our work:

- Correlations of coverage dependence of oxygen adsorption on different metals [30, 31]

---

## Adsorption energy at 1ML

---

```

1  from jasp import *
2
3  with jasp('surfaces/Pt-slab-1x1-0-fcc') as calc:
4      atoms = calc.get_atoms()
5      e_slab_o = atoms.get_potential_energy()
6
7  # clean slab
8  with jasp('surfaces/Pt-slab-1x1') as calc:
9      atoms = calc.get_atoms()
10     e_slab = atoms.get_potential_energy()
11
12  with jasp('molecules/O2-sp-triplet-350') as calc:
13      atoms = calc.get_atoms()
14      e_O2 = atoms.get_potential_energy()
15
16  hads = e_slab_o - e_slab - 0.5*e_O2
17  print 'Hads (1ML) = {0:1.3f} eV'.format(hads)

```

---

Hads (1ML) = -0.099 eV

The adsorption energy is **much** less favorable at 1ML coverage than at 0.25 ML coverage! We will return what this means in [Atomistic thermodynamics effect on adsorption](#).

### 5.6.3 Effect of adsorption on the surface energy

There is a small point to make here about what adsorption does to surface energies. Let us define a general surface formation energy scheme like this:

Figure 16: Schematic of forming a surface with adsorbates.

Let us presume the surfaces are symmetric, and that each surface contributes half of the energy change. The overall change in energy:

$$\Delta E = E_{slab,ads} - E_{ads} - E_{bulk}$$

where the the energies are appropriately normalized for the stoichiometry. Let us rearrange the terms, and add and subtract a constant term  $E_{slab}$ .

$$\Delta E = E_{slab,ads} - E_{slab} - E_{ads} - E_{bulk} + E_{slab}$$

We defined  $\gamma_{clean} = \frac{1}{2A}(E_{slab} - E_{bulk})$ , and we defined  $H_{ads} = E_{slab,ads} - E_{slab} - E_{ads}$  for adsorption on a single side of a slab. In this case, there are adsorbates on both sides of the slab, so  $E_{slab,ads} - E_{slab} - E_{ads} = 2\Delta H_{ads}$ . If we normalize by  $2A$ , the area for both sides of the slab, we get

$$\frac{\Delta E}{2A} = \gamma = \gamma_{clean} + \frac{H_{ads}}{A}$$

You can see here that the adsorption energy serves to stabilize, or reduce the surface energy, provided that the adsorption energy is negative.

Some final notes about the equations above:

- We were not careful about stoichiometry. As written, it is assumed there are the same number of atoms (not including the adsorbates) in the slabs and bulk, and the same number of adsorbate atoms in the slab and  $E_{ads}$ . Appropriate normalization factors must be included if that is not true.
- It is not necessary to perform a symmetric slab calculation to determine the effect of adsorption on the surface energy! You can examine  $\gamma - \gamma_{clean}$  with knowledge of only the adsorption energies!

## 5.7 TODO Adsorbate vibrations

# 6 Atomistic thermodynamics

Let's consider how much the Gibbs free energy of an O<sub>2</sub> molecule changes as a function of temperature, at 1 atm. We use the Shomate polynomials to approximate the temperature dependent entropy and enthalpy, and use the parameters from the [Nist Webbook](#) for O<sub>2</sub>.

---

```
1 import numpy as np
2 import matplotlib.pyplot as plt
3 from ase.units import *
4 K = 1. #not defined in ase.units!
5
6 # Shomate parameters
7 A = 31.32234; B = -20.23531; C = 57.86644
8 D = -36.50624; E = -0.007374; F = -8.903471
9 G = 246.7945; H = 0.0
10
11 def entropy(T):
12     '''entropy returned as eV/K
13     T in K
14     '''
15     t = T/1000.
16     s = A*np.log(t) + B*t + C*(t**2)/2. + D*(t**3)/3. - E/(2.*t**2) + G
17     return s*J/mol/K
18
19 def enthalpy(T):
20     ''' H - H(298.15) returned as eV/molecule'''
21     t = T/1000.
22     h = A*t + B*(t**2)/2. + C*(t**3)/3. + D*(t**4)/4. - E/t + F - H
23     return h*kJ/mol
24
25 T = np.linspace(100,700)
26
27 G = enthalpy(T) - T*entropy(T)
28
29 plt.plot(T,G)
30 plt.xlabel('Temperature (K)')
31 plt.ylabel('$\Delta G^\text{circ}$ (eV)')
32 plt.savefig('images/O2-mu.png')
```

Figure 17: Effect of temperature on the Gibbs free energy of an O2 molecule at 1 atm.

This is clearly a big effect! Between 500-600K, the energy has dropped by nearly 1 eV.

```

1 import matplotlib.pyplot as plt
2 import numpy as np
3 from ase.units import *
4
5 atm = 101325*Pascal #atm is not defined in units
6 K = 1
7
8 # examine range over 10^-10 to 10^10 atm
9 P = np.logspace(-10,10)*atm
10
11 plt.semilogx(P/atm, kB*(300*K)*np.log(P/(1*atm)),label='300K')
12 plt.semilogx(P/atm, kB*(600*K)*np.log(P/(1*atm)),label='600K')
13 plt.xlabel('Pressure (atm)')
14 plt.ylabel('$\Delta G$ (eV)')
15 plt.legend(loc='best')
16 plt.savefig('images/O2-g-p.png')

```

Figure 18: Effects of pressure on the ideal gas Gibbs free energy

Similarly, you can see that simply changing the pressure has a large effect on the Gibbs free energy of an ideal gas through the term:  $kT \ln(P/P_0)$ , and that this effect is also temperature dependent. This leads us to the final formula we will use for the chemical potential of oxygen:

$$\mu_{O_2} = E_{O_2}^{DFT} + E_{O_2}^{ZPE} + \Delta\mu(T) + kT \ln(P/P_0)$$

## 6.1 bulk phase stability of oxides

We will consider the effects of oxygen pressure and temperature on the formation energy of  $Ag_2O$  and  $Cu_2O$ .

In atomistic thermodynamics, we define the free energy of formation as:

We define the formation energy as:

$$G_f = G_{Cu_2O} - 2G_{Cu} - 0.5G_{O_2}$$

We will at this point assume that the solids are incompressible, and that  $S_{Cu_2O} - 2S_{Cu} \approx 0$ , which leads to  $G_{Cu_2O} - 2G_{Cu} \approx E_{Cu_2O} - 2E_{Cu}$ , which we directly compute from DFT. We express  $G_{O_2} = \mu_{O_2} = E_{O_2}^{DFT} + E_{O_2}^{ZPE} + \Delta\mu(T) + kT \ln(P/P_0)$ . In this example we neglect the zero-point energy of the oxygen molecule, and finally arrive at:

$$G_f \approx E_{Cu_2O} - 2E_{Cu} - 0.5(E_{O_2}^{DFT} + \delta\mu(T) + kT \ln(P/P_0))$$

Which, after grouping terms is:

$$G_f \approx E_{Cu_2O} - 2E_{Cu} - 0.5(E_{O_2}^{DFT}) - 0.5 * \Delta\mu_{O_2}(P, T)$$

with  $\Delta\mu_{O_2}(P, T) = \delta\mu(T) + kT \ln(P/P_0)$ . We get  $\delta\mu(T)$  from the Janaf Tables, or the NIST Webbook.

You will recognize in this equation the standard formation energy we calculated in Metal oxide formation energies, plus a correction for the non standard state pressure and temperature ( $\Delta\mu_{O_2}(P, T) = 0$  at standard state).

$$G_f \approx H_f - 0.5 * \Delta\mu_{O_2}(P, T)$$

The formation energy of Cu<sub>2</sub>O is -1.9521 eV/formula unit. The formation energy for Ag<sub>2</sub>O is -0.99 eV/formula unit. Let us consider what temperature the oxides decompose at a fixed oxygen pressure of 1e-10 atm. We need to find the temperature where:

$$H_f = 0.5 * \Delta\mu_{O_2}(P, T)$$

which will make the formation energy be 0.

19  plt.show()

```

---

This graph shows graphically the  $\Delta\mu$  required to make the metal more

stable than the oxide. Anything less than about -2 eV will have the metal more stable. That can be achieved by any one of the following combinations (graphically estimated from Figure 19): About 500K at 1e-10 atm, 600K at 1e-5 atm, 900K at 1atmm, etc...

## 6.2 TODO Effect on adsorption

We now consider the question: Given a pressure and temperature, what coverage would you expect on a surface? We saw earlier that adsorption energies depend on the site and coverage. We also know the coverage depends on the pressure and temperature. Above some temperature, desorption occurs, and below some pressure adsorption will not be favorable. We seek to develop a quantitative method to determine those conditions.

We redefine the adsorption energy as:

$$\Delta G_{ads} \approx E_{slab,ads} - E_{slab} - \mu_{ads}$$

where again we neglect all contributions to the free energy of the slabs from vibrational energy and entropy, as well as configurational entropy if that is relevant. That leaves only the pressure and temperature dependence of the adsorbate, which we treat in the ideal gas limit.

We expand  $\mu_{ads}$  as  $E_{ads} + \Delta\mu(T, p)$ , and thus:

$$\Delta G_{ads} \approx E_{slab,ads} - E_{slab} - E_{ads} - \Delta\mu(T, p)$$

or

$$\Delta G_{ads} \approx \Delta H_{ads} - \Delta\mu(T, p)$$

where  $\Delta H_{ads}$  is the adsorption energy we defined earlier. Now we can examine the effect of  $\Delta\mu(T, p)$  on the adsorption energies. We will use the adsorption energies for the oxygen on Pt(111) system we computed earlier:

system	$\Delta H(eV/O)$
fcc (0.25 ML)	-1.04
hcp (0.25 ML)	-0.60
bridge (0.25 ML)	-0.49
fcc(1ML)	-0.10

---

```

1 import numpy as np
2 import matplotlib.pyplot as plt
3
4 fcc25 = -1.04
5 hcp25 = -0.60
6 bridge25 = -0.49
7 fcc1 = -0.10
8
9 Dmu = np.linspace(-4,0)
10
```

```

### 6.3 TODO multiple reactions

In [44] we considered multiple reactions in an atomistic thermodynamic framework. Let us consider these three reactions of dissociative adsorption of hydrogen and hydrogen disulfide, and consider how to compute the reaction energy for the third reaction.

1.  $H_2 + 2* \rightleftharpoons 2H*$
2.  $H_2S + 2* \rightleftharpoons H* + SH*$
3.  $SH* + * \rightleftharpoons S* + H*$

The reaction energy of interest is  $E_{rxn} = \mu_{S*} + \mu_{H*} - \mu_{SH*}$ . The question is, what are these chemical potentials? We would like them in terms of pressures and temperature, preferably of molecules that can be approximated as ideal gases. By equilibrium arguments we can say that  $\mu_{H*} = \frac{1}{2}\mu_{H_2}$ . It follows that at equilibrium:

$\mu_{H*} + \mu_{SH*} = \mu_{H_2S}$  and  $\mu_{S*} + \mu_{S*} = \mu_{SH*}$ . From the first equation we have:

$$\mu_{SH*} = \mu_{H_2S} - \frac{1}{2}\mu_{H_2}$$

and from the second equation we have:

$$\mu_{S*} = \mu_{SH*} - \mu_{H*} = \mu_{H_2S} - \mu_{H_2}.$$

Thus, the chemical potentials of all these three adsorbed species depend on the chemical potentials of two gas-phase species. The chemical potentials of each of these gases can be defined as:

$$\mu_{gas}(T, p) = E_{gas}(0K) + \delta\mu + kT \ln(p/p^0), \text{ as we have defined before.}$$

## 7 Advanced electronic structure methods

### 7.1 DFT+U

[VASP manual on DFT+U](#)

#### 7.1.1 Metal oxide oxidation energies with DFT+U

We will reconsider here the reaction (see [Metal oxide oxidation energies](#))  $2Cu_2O + O_2 \rightleftharpoons 4CuO$ . We need to compute the energy of each species, now with DFT+U. In [43] they use a U parameter of 4 eV for Cu which gave the best agreement with the experimental value. We will also try that.

#### Cu2O calculation with U=4.0

---

```

1  from jasp import *
2
3  from ase.visualize import *
4  from ase import Atom, Atoms
5

7      calc.clone('bulk/Cu2O-U=4.0')
8
9  with jasp('bulk/Cu2O-U=4.0') as calc:
10     calc.set(ldau=True, # turn DFT+U on
11              ldautype=2, # select simplified rotationally invariant option
12              ldau_luj={'Cu':{'L':2, 'U':4.0, 'J':0.0},
13                       'O':{'L':-1, 'U':0.0, 'J':0.0}},
14              ldauprint=1,
```

```

15         ibrion=-1, #do not rerelex
16         nsw=0)
17     atoms = calc.get_atoms()
18     print atoms.get_potential_energy()
19     print calc

```

---

```

1 grep -A 3 "LDA+U is selected, type is set to LDAUTYPE" bulk/Cu2O-U=4.0/OUTCAR

```

---

## CuO calculation with U=4.0

---

```

1 from jasp import *
2
3 from ase.visualize import *
4 from ase import Atom, Atoms
5
6 with jasp('bulk/CuO') as calc:
7     calc.clone('bulk/CuO-U=4.0')
8
9 with jasp('bulk/CuO-U=4.0') as calc:
10     calc.set(ldau=True, # turn DFT+U on
11             ldautype=2, # select simplified rotationally invariant option
12             ldau_luj={'Cu':{'L':2, 'U':4.0, 'J':0.0},
13                     'O':{'L':-1, 'U':0.0, 'J':0.0}},
14             ldauprint=1,
15             ibrion=-1, #do not rerelex
16             nsw=0)
17     atoms = calc.get_atoms()
18     print atoms.get_potential_energy()
19     print calc

```

---

## Reaction energy calculation with DFT+U

---

```

1 from jasp import *
2
3 # don't forget to normalize your total energy to a formula unit. Cu2O has 3 atoms, so the number of formula units in
4 with jasp('bulk/Cu2O-U=4.0') as calc:
5     atoms = calc.get_atoms()
6     cu2o_energy = atoms.get_potential_energy()/(len(atoms)/3)
7
8 with jasp('bulk/CuO-U=4.0') as calc:
9     atoms = calc.get_atoms()
10    cuo_energy = atoms.get_potential_energy()/(len(atoms)/2)
11
12 # make sure to use the same cutoff energy for the O2 molecule!
13 with jasp('molecules/O2-sp-triplet-400') as calc:
14     atoms = calc.get_atoms()
15     o2_energy = atoms.get_potential_energy()
16
17 rxn_energy = 4.0*cuo_energy - o2_energy - 2.0*cu2o_energy
18 print rxn_energy
19 print rxn_energy - 1.36

```

---

This is still not in quantitative agreement with the result in [43], which at  $U=4$  eV is about -3.14 eV (estimated from a graph). We have not applied the  $O_2$  correction here yet. In that paper, they apply a constant shift of -1.36 eV per  $O_2$ . After we apply that correction, we agree within 0.12 eV, which is pretty good considering we have not checked for convergence.

### How much does $U$ affect the reaction energy?

---

```

1 from jasp import *
2 JASPRC['mode'] = 'run'
3 for U in [2.0, 4.0, 6.0]:
4     ## Cu2O #####
5     with jasp('bulk/Cu2O') as calc:
6         calc.clone('bulk/Cu2O-U={0}'.format(U))
7
8     with jasp('bulk/Cu2O-U={0}'.format(U)) as calc:
9         calc.set(ldau=True, # turn DFT+U on
10                 ldautype=2, # select simplified rotationally invariant option
11                 ldau_luj={'Cu':{'L':2, 'U':U, 'J':0.0},
12                           'O':{'L':-1, 'U':0.0, 'J':0.0}},
13                 ldauprint=1,
14                 ibrion=-1, #do not rerelex
15                 nsw=0)
16         atoms = calc.get_atoms()
17         cu2o_energy = atoms.get_potential_energy()/(len(atoms)/3)
18
19     ## CuO #####
20     with jasp('bulk/CuO') as calc:
21         calc.clone('bulk/CuO-U={0}'.format(U))
22
23     with jasp('bulk/CuO-U={0}'.format(U)) as calc:
24         calc.set(ldau=True, # turn DFT+U on
25                 ldautype=2, # select simplified rotationally invariant option
26                 ldau_luj={'Cu':{'L':2, 'U':U, 'J':0.0},
27                           'O':{'L':-1, 'U':0.0, 'J':0.0}},
28                 ldauprint=1,
29                 ibrion=-1, #do not rerelex
30                 nsw=0)
31         atoms = calc.get_atoms()
32         cuo_energy = atoms.get_potential_energy()/(len(atoms)/2)
33
34     ## O2 #####
35     # make sure to use the same cutoff energy for the O2 molecule!
36     with jasp('molecules/O2-sp-triplet-400') as calc:
37         atoms = calc.get_atoms()
38         o2_energy = atoms.get_potential_energy()
39
40     rxn_energy = 4.0*cuo_energy - o2_energy - 2.0*cu2o_energy
41     print 'U = {0} reaction energy = {1}'.format(U,rxn_energy - 1.99)

```

---

In [43], the difference in reaction energy from  $U=2$  eV to  $U=4$  eV was about 0.5 eV (estimated from graph). Here we see a range of 0.48 eV from

U=2 eV to U=4 eV. Note that for U=0 eV, we had a (corrected reaction energy of -3.96 eV). Overall, the effect of adding U decreases this reaction energy.

This example highlights the challenge of using an approach like DFT+U. On one hand, U has a clear effect of changing the reaction energy. On the other hand, so does the correction factor for the O2 binding energy. In [43] the authors tried to get the O2 binding energy correction from oxide calculations where U is not important, so that it is decoupled from the non-cancelling errors that U fixes. See [16] for additional discussion of how to mix GGA and GGA+U results.

## 7.2 Hybrid functionals

### 7.2.1 FCC Ni DOS

maybe Mike Widom can show me how he did this with VASP?

# 8 **Acknowledgments**

I would like to thank Zhongnan Xu for sending me some examples on magnetism. Alan McGaughey for sending me some NEB examples.

# 9 **Appendices**

## 9.1 **Recipes**

### 9.1.1 **Modifying Atoms by deleting atoms**

Sometimes it is convenient to create an Atoms object by deleting atoms from an existing object. Here is a recipe to delete all the hydrogen atoms in a molecule. The idea is to make a list of indices of which atoms to delete using list comprehension, then use list deletion to delete those indices.

---

```
1  from ase.data.molecules import molecule
2  atoms = molecule('CH3CH2OH')
3  print atoms
4
5  ind2del = [atom.index for atom in atoms if atom.symbol=='H']
6  print ind2del
7
8  del atoms[ind2del]
9  print atoms
```

---

### 9.1.2 **Using units in ase**

ase uses a base set of atomic units. Other units are defined in terms of those units, and you can easily convert to alternative units by dividing your quantity in atomic units by the units you want.

Not too many units are defined: ['A', 'AUT', 'Ang', 'Angstrom', 'Bohr', 'C', 'Debye', 'GPa', 'Ha', 'Hartree', 'J', 'Pascal', 'Ry', 'Rydberg', 'alpha', 'cm', 'eV', 'erg', 'fs', 'kB', 'kJ', 'kcal', 'kg', 'm', 'meV', 'mol', 'nm', 's', 'second']

it is not that hard to define your own derived units though.

Note these are only conversion factors. No unit algebra is enforced!

---

```
1  #!/usr/bin/env python
2  from ase.units import *
3
4  d = 1*Angstrom
5  print d/nm
6
7  print '1 eV = %f Hartrees' % (eV/Hartree)
8  print '1 eV = %f Rydbergs' % (eV/Rydberg)
9  print '1 eV = %f kJ/mol' % (eV/(kJ/mol))
10 print '1 eV = %f kcal/mol' % (eV/(kcal/mol))
11
12 print '1 Hartree = %f kcal/mol' % (1*Hartree/(kcal/mol))
13 print '1 Rydberg = %f eV' % (1*Rydberg/eV)
14
15 # derived units
16 minute = 60*s
17 hour = 60*minute
18
19 #convert 10 hours to minutes
20 print 10*hour/minute
```

---

### 9.1.3 numpy arrays

See <http://www.scipy.org/Cookbook/BuildingArrays> for examples of making numpy arrays.

#### 4.1.1. Extracting parts of an array

When analyzing numerical data you may often want to analyze only a part of the data. For example, suppose you have x and y data, (x=time, y=signal) and you want to integrate the data between a particular time interval. You can slice a numpy array to extract parts of it. See <http://www.scipy.org/Cookbook/Indexing> for several examples of this.

In this example we show how to extract the data in an interval. We have x data in the range of 0 to 6, and y data that is the cos(x). We want to extract the x and y data for  $2 \leq x \leq 4$ , and the corresponding y-data. To do this, we utilize the numpy capability of slicing with a boolean array. We also show some customization of matplotlib.

---

```
1  #!/usr/bin/env python
2
```

```

3 import numpy as np
4 import matplotlib as mpl
5 #http://matplotlib.sourceforge.net/users/customizing.html
6 mpl.rcParams['legend.numpoints'] = 1 #default is 2
7 from pylab import *
8
9 x = np.linspace(0,6,100)
10 y = np.cos(x)
11
12 plot(x,y,label='full')
13
14 ind = (x>2) & (x<4)
15
16 subx = x[ind]
17 suby = y[ind]
18
19 plot(subx,suby,'bo',label='sliced')
20 xlabel('x')
21 ylabel('cos(x)')
22 legend(loc='lower right')
23 savefig('images/np-array-slice.png')

```

---

The expression `x[2]` returns an array of booleans (True where the element of `x` is greater than 2, and False where it is not) equal in size to `x`. Similarly `x[4]` returns a boolean array where `x` is less than 4. We take the logical and `&` of these two boolean arrays to get another boolean array where both conditions are True (i.e. `x[2]` and `x[4]`). This final boolean array is True for the part of the arrays we are interested in, and we can use it to extract the subarrays

we want.

#### 9.1.4 Statistics

##### Confidence intervals

---

```
1  #!/usr/bin/env python
2  from numpy import *
3  from scipy.stats.distributions import t
4
5
6  n = 10 #number of measurements
7  dof = n - 1 #degrees of freedom
8  avg_x = 16.1 #average measurement
9  std_x = 0.01 #standard deviation of measurements
10
11 #Find 95% prediction interval for next measurement
12
13 alpha = 1.0 - 0.95
14
15 pred_interval = t.ppf(1-alpha/2.,dof)*std_x*sqrt(1.+1./n)
16
17 print 'We are 95%% confident the next measurement will be between %1.3f and %1.3f' % (avg_x - pred_interval, avg_x + pred_interval)
```

---

#### 9.1.5 Curve fitting

##### Linear fitting

---

```
1  #examples of linear curve fitting using least squares
2  import numpy as np
3
4  xdata = np.array([0.,1.,2.,3.,4.,5.,6.])
5  ydata = np.array([0.1, 0.81, 4.03, 9.1, 15.99, 24.2, 37.2])
6
7  #fit a third order polynomial
8  from pylab import polyfit, plot, show, legend, savefig
9  pars = polyfit(xdata,ydata,3)
10 print pars
11
12 ## numpy method returns more data
13 A = np.column_stack([xdata**3,xdata**2,xdata,np.ones(len(xdata),np.float)])
14 pars_np,resids,rank,s = np.linalg.lstsq(A,ydata)
15 print pars_np
16
17 '''
18 we are trying to solve  $Ax = b$  for  $x$  in the least squares sense. There
19 are more rows in  $A$  than elements in  $x$  so, we can left multiply each
20 side by  $A^T$ , and then solve for  $x$  with an inverse.
21
22  $A^T A x = A^T b$ 
23  $x = (A^T A)^{-1} A^T b$ 
24 '''
```

```

25 # not as pretty but equivalent!
26 pars_man= np.dot(np.linalg.inv(np.dot(A.T,A)), np.dot(A.T,ydata))
27 print pars_man
28
29 #but, it is easy to fit an exponential function to it!
30 # y = a*exp(x)+b
31 Aexp = np.column_stack([np.exp(xdata), np.ones(len(xdata),np.float)])
32 pars_exp=np.dot(np.linalg.inv(np.dot(Aexp.T,Aexp)), np.dot(Aexp.T,ydata))
33
34 plot(xdata,ydata,'ro')
35 fity = np.dot(A,pars)
36 plot(xdata,fity,'k-',label='poly fit')
37 plot(xdata,np.dot(Aexp,pars_exp),'b-',label='exp fit')
38 legend()
39 savefig('images/curve-fit-1.png')

```

---

### 9.1.8 TODO Interpolation in 3D

You might ask, why would I need to interpolate in 3D? Suppose you want to plot the charge density along a line through a unit cell that does not correspond to grid points? What are you to do? Interpolate. In contrast to an abundance of methods for 1D and 2D interpolation, I could not find any standard library methods for 3D interpolation. The Scipy cookbook on interpolation suggests that it should be doable with `ndimage`, but I could not figure out how to make those examples work.

The principle we will use to develop an interpolation function in 3D is called trilinear interpolation, where we use multiple linear 1D interpolations to compute the value of a point inside a cube. As developed here, this solution only applies to rectangular grids. Later we will generalize the approach. We state the problem as follows:

we know a scalar field inside a unit cell on a regularly spaced grid. In Dacapo these fields may be the charge density or electrostatic potential for example, and they are known on the fft grids. we want to estimate the value of the scalar field at a point not on the grid, say  $P=(a,b,c)$ .

Solution: Find the cube that contains the point, and is defined by points P1-P8 as shown in Figure Trilinear interpolation.

In a trilinear interpolation scheme in a cell we perform several interpo-

Figure 21: Trilinear interpolation scheme.

lations. The red lines are 1D interpolations in  $x$  along constant  $y$ , and  $z$ . The light blue lines are 1D interpolations in  $y$  along constant  $x=a$ ,  $z$ , and the vertical dark line through  $P$  is the final interpolation at constant  $x=a$ ,  $y=b$  in  $z$ .

Now, we use 1D interpolation formulas to compute the value of the scalar field at points  $I1$  by interpolating between  $P1$  and  $P2$ , and the value of the scalar field at  $I2$  by interpolating between  $P3$  and  $P4$ . In these points the only variable changing is  $x$ , so it is a simple 1D interpolation. We can then compute the value of the scalar field at  $I5$  by interpolating between  $I1$  and  $I2$ . We repeat the process on the top of the cube, to obtain points  $I3$ ,  $I4$  and  $I5$ . Finally, we compute the value of the scalar field at point  $P$  by interpolating between points  $I5$  and  $I6$ . Note that the point  $I5$  has coordinates  $(a,b,z1)$

and (a,b,z2), so the final interpolation is again a 1D interpolation along z evaluated at z=c to get the final value of the scalar field at P=(a,b,c).

105    plot([cR,cR],[0,2],'r-') #markers for where the nuclei are
106    plot([oR,oR],[0,8],'r-')
107    xlabel('|R| ($\AA$)')
108    ylabel('Charge density (e/$\AA^3$)')

```

```

109 savefig('images/C0-charge-density.png')
110 show()

```

---

To generalize this to non-cubic cells, we need to do interpolation along arbitrary vectors. The overall strategy is the same:

Find the cell that contains the point (a,b,c). compute the scaled coordinates (sa,sb,sc) of the point inside the cell. Do the interpolations along the basis vectors. Given u1 at P1(x1,y1,z1) and u2 at P2(x2,y2,z2) where (P2-P1) is a cell basis vector a,  $u = u1 + sa*(u2-u1)$ . There are still 7 interpolations to do.

Below is an example of this code, using a the python library bisect to find the cell.

---

```

1  '''
2  3D vector interpolation in non-cubic unit cells with vector
3  interpolation.
4
5  This function should work for any shape unit cell.
6  '''

93 xlabel('|R| ($\AA$)')
94 ylabel('Charge density (e/$\AA^3$)')
95 show()

```

---

### 9.1.9 Reading and writing data

**Builtin io modules** “pylab” has two convenient and powerful functions for saving and reading data, :func:‘pylab.save’ and :func:‘pylab.load’.

---

```

1 pylab.save('pdat.dat', (x,y))

```

---

and later you can read these arrays back in with:

---

```

1 x,y = pylab.load('pdat.dat')

```

---

see also :func:‘pylab.csv2rec’ and :func:‘pylab.loadtxt’ and :func:‘pylab.savetxt’.

See <http://www.scipy.org/Cookbook/InputOutput> for examples of numpy io.

**From scratch** You can save data in many ways from scratch. Basically, just open a file and write data to it. Likewise, any datafile that has some structure to it can probably be read by python.

Reading a datafile with ::

`#header #ignore these lines john, 4 robert, 5 terry, 5`

A standard approach would be to read in all the lines, skip the first two lines, split each line (remember each line is a string) at the ‘,’ and append the first field to one variable, and append the second field to another variable as an integer. For example::

---

```
1 v1 = []
2 v2 = []
3 lines = open('somefile','r').readlines()
4
5 for line in lines[2:]: #skip the first two lines
6     fields = line.split(',')
7     v1.append(fields[0]) #names
8     v2.append(int(fields[1])) #number
```

---

Writing datafiles is easy too.

---

```
1 v1 = ['john','robert','terry']
2 v2 = [4,5,6]
3 f = open('somefile', 'w') #note 'w' = write mode
4 f.write('#header\n')
5 f.write('#ignore these lines\n')
6 for a,b in zip(v1,v2):
7     f.write('%s, %i\n' % (a,b))
8 f.close()
```

---

Some notes:

1. opening a file in ‘w’ mode clobbers any existing file, so do that with care!

1. when writing to a file you have to add  
n to each line. this is the

carriage return.

1. Manually writing and reading files is pretty tedious. Whenever possible you should use the builtin methods of numpy or pylab.

### 9.1.10 Integration

Numerical integrations is easy with the `numpy.trapz()` method. Use it like this: `numpy.trapz(y,x)`. Note that `y` comes first. `y` and `x` must be the same length.

Integration can be used to calculate average properties of continuous distributions. Suppose for example, we have a density of states,  $\rho$  as a function of energy  $E$ . We can integrate the density of states to find the total number of states:

$$N_{states} = \int \rho dE$$

or, in python:

```
!!! Nstates = np.trapz(rho,E)
```

where `rho` is a vector that contains the density of states at each energy in the vector `E` (vector here means a list of numbers).

The average energy of distribution is:

$$E_{avg} = \frac{\int \rho E dE}{\int \rho dE}$$

or, in python:

```
!!! e_avg = np.trapz(rho*E,E)/np.trapz(rho,E)
```

These last two examples are the zeroth and first moments of the density of states. The second moment is related to the width squared of the distribution, and the third and fourth moments are related to skewness and kurtosis of the distribution.

The  $n$ th moment is defined by:

$$m_n = \frac{\int \rho E^n dE}{\int \rho dE}$$

To get the second moment of the density of states in python, we use::

```
!!! n = 2 !!! mom_2 = np.trapz(rho*E**n,E)/np.trapz(rho,E)
```

### 9.1.11 Numerical differentiation

`numpy` has a function called `numpy.diff()` that is similar to the one found in `matlab`. It calculates the differences between the elements in your list, and returns a list that is one element shorter, which makes it unsuitable for plotting the derivative of a function.

#### 4.3.1. Simple loops to define finite difference derivatives

Loops in python are pretty slow (relatively speaking) but they are usually trivial to understand. In this script we show some simple ways to construct derivative vectors using loops. It is implied in these formulas that the data points are equally spaced.

```

1  import numpy as np
2  from pylab import *
3  import time
4
5  '''
6  These are the brainless way to calculate numerical derivatives. They
7  work well for very smooth data. they are surprisingly fast even up to
8  10000 points in the vector.
9  '''
10
11 x = np.linspace(0.78,0.79,100)
12 y = np.sin(x)
13 dy_analytical = np.cos(x)
14 '''
15 lets use a forward difference method:
16 that works up until the last point, where there is not
17 a forward difference to use. there, we use a backward difference.
18 '''
19
20 tf1 = time.time()
21 dyf = [0.0]*len(x)
22 for i in range(len(y)-1):
23     dyf[i] = (y[i+1] - y[i])/(x[i+1]-x[i])
24 #set last element by backwards difference
25 dyf[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
26
27 print ' Forward difference took %1.1f seconds' % (time.time() - tf1)
28
29 '''and now a backwards difference'''
30 tb1 = time.time()
31 dyb = [0.0]*len(x)
32 #set first element by forward difference
33 dyb[0] = (y[0] - y[1])/(x[0] - x[1])
34 for i in range(1,len(y)):
35     dyb[i] = (y[i] - y[i-1])/(x[i]-x[i-1])
36
37 print ' Backward difference took %1.1f seconds' % (time.time() - tb1)
38
39 '''and now, a centered formula'''
40 tc1 = time.time()
41 dyc = [0.0]*len(x)
42 dyc[0] = (y[0] - y[1])/(x[0] - x[1])
43 for i in range(1,len(y)-1):
44     dyc[i] = (y[i+1] - y[i-1])/(x[i+1]-x[i-1])
45 dyc[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
46
47 print ' Centered difference took %1.1f seconds' % (time.time() - tc1)
48
49 '''
50 the centered formula is the most accurate formula here
51 '''
52
53 plot(x,y)
54 plot(x,dy_analytical,label='analytical derivative')
55 plot(x,dyf,'--',label='forward')
56 plot(x,dyb,'--',label='backward')

```

```

57 plot(x,dyc,'--',label='centered')
58
59 legend(loc='lower left')
60 savefig('images/simple-diffs.png')
61 show()

```

---

Loops are usually not great for performance. Numpy offers some vectorized methods that allow us to compute derivatives without loops, although this comes at the mental cost of harder to understand syntax:

---

```

1 import numpy as np
2 from pylab import *
3
4 x = np.linspace(0,2*np.pi,100)
5 y = np.sin(x)
6 dy_analytical = np.cos(x)
7
8
9 # we need to specify the size of dy ahead because diff returns
10 #an array of n-1 elements
11 dy = np.zeros(y.shape,np.float) #we know it will be this size
12 dy[0:-1] = np.diff(y)/np.diff(x)
13 dy[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
14
15
16 '''
17 calculate dy by center differencing using array slices
18 '''

```

```

19
20 dy2 = np.zeros(y.shape,np.float) #we know it will be this size
21 dy2[1:-1] = (y[2:] - y[0:-2])/(x[2:] - x[0:-2])
22 dy2[0] = (y[1]-y[0])/(x[1]-x[0])
23 dy2[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
24
25 plot(x,y)
26 plot(x,dy_analytical,label='analytical derivative')
27 plot(x,dy,label='forward diff')
28 plot(x,dy2,'k--',lw=2,label='centered diff')
29 legend(loc='lower left')
30 savefig('images/vectorized-diffs.png')
31 show()

```

---

If your data is very noisy, you will have a hard time getting good derivatives; derivatives tend to magnify noise. In these cases, you have to employ smoothing techniques, either implicitly by using a multipoint derivative formula, or explicitly by smoothing the data yourself, or taking the derivative of a function that has been fit to the data in the neighborhood you are interested in.

Here is an example of a 4-point centered difference of some noisy data:

---

```

1 import numpy as np
2 from pylab import *
3
4 x = np.linspace(0,2*np.pi,100)

```

```

5  y = np.sin(x) + 0.1*np.random.random(size=x.shape)
6  dy_analytical = np.cos(x)
7
8  #2-point formula
9  dyf = [0.0]*len(x)
10 for i in range(len(y)-1):
11     dyf[i] = (y[i+1] - y[i])/(x[i+1]-x[i])
12 #set last element by backwards difference
13 dyf[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
14
15 '''
16 calculate dy by 4-point center differencing using array slices
17
18 
$$\frac{y[i-2] - 8y[i-1] + 8y[i+1] - y[i+2]}{12h}$$

19
20 y[0] and y[1] must be defined by lower order methods
21 and y[-1] and y[-2] must be defined by lower order methods
22 '''
23
24 dy = np.zeros(y.shape,np.float) #we know it will be this size
25 h = x[1]-x[0] #this assumes the points are evenly spaced!
26 dy[2:-2] = (y[0:-4] - 8*y[1:-3] + 8*y[3:-1] - y[4:])/(12.*h)
27
28 dy[0] = (y[1]-y[0])/(x[1]-x[0])
29 dy[1] = (y[2]-y[1])/(x[2]-x[1])
30 dy[-2] = (y[-2] - y[-3])/(x[-2] - x[-3])
31 dy[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
32
33
34 plot(x,y)
35 plot(x,dy_analytical,label='analytical derivative')
36 plot(x,dyf,'r-',label='2pt-forward diff')
37 plot(x,dy,'k--',lw=2,label='4pt-centered diff')
38 legend(loc='lower left')
39 savefig('images/multipt-diff.png')
40 show()

```

---

The derivative is still noisy, but the four-point derivative is a little better than the two-pt formula.

**FFT derivatives** It is possible to perform derivatives using FFT:

---

```

1  import numpy as np
2  from pylab import *
3
4  N = 101 #number of points
5  L = 2*np.pi #interval of data
6
7  x = np.arange(0.0,L,L/float(N)) #this does not include the endpoint
8
9  #add some random noise
10 y = np.sin(x) + 0.05*np.random.random(size=x.shape)
11 dy_analytical = np.cos(x)
12
13 '''
14 http://sci.tech-archive.net/Archive/sci.math/2008-05/msg00401.html
15
16 you can use fft to calculate derivatives!
17 '''
18
19 if N % 2 == 0:
20     k = np.asarray(range(0,N/2)+[0] + range(-N/2+1,0))
21 else:
22     k = np.asarray(range(0,(N-1)/2) + [0] + range(-(N-1)/2,0))
23

```

```

24 k *= 2*np.pi/L
25
26 fd = np.fft.ifft(1.j*k * np.fft.fft(y))
27
28 plot(x,y)
29 plot(x,dy_analytical,label='analytical der')
30 plot(x,fd,label='fft der')
31 legend(loc='lower left')
32
33 savefig('images/fft-der.png')
34 show()

```

---

This example does not show any major advantage in the quality of the derivative, and it is almost certain I would never remember how to do this off the top of my head.

### 9.1.12 NetCDF files

[NetCDF](#) is a binary, but cross-platform structured data format. The input file and output file for Dacapo is the NetCDF format. On creating a NetCDF file you must define the dimensions and variables before you can store data in them. You can create and read NetCDF files in python using one of the following modules:

(<http://dirac.cnrs-orleans.fr/plone/software/scientificpython/>)  
:mod:`netCDF3` (<http://netcdf4-python.googlecode.com/svn/trunk/docs/netCDF3-module.html>)

`:mod: 'pycdf'` (<http://pysclint.sourceforge.net/pycdf/>) this is a very low level module modelled after the C-api. I am not sure it is completely bug-free (I have problems with character variables)

I suggest you read through the `jacapo.py` code for many examples of reading and writing NetCDF files.

### 9.1.13 python modules

the comma separated values (`:mod: 'csv'`) module in python allows you to easily create datafiles:

“csv” writing::

```
import numpy as np
x = np.linspace(0.0,6.0,100) y = np.cos(x)
import csv writer = csv.writer(open("some.csv", "w")) writer.writerows(zip(x,y))
```

It is not so easy to read the data back in though because the module only returns strings, so you must turn the strings back into floats (or whatever other format they should be).

“csv” reading::

```
import csv reader = csv.reader(open("some.csv", 'r'), delimiter=',')
x,y = [],[] for row in reader: #csv returns strings that must be cast as
floats a,b = [float(z) for z in row] x.append(a) y.append(b)
```

This is almost as much work as manually reading the data though. The module is more powerful than I have shown here, so one day checkout “`pydoc csv`”

The `:mod: 'pickle'` and `:mod: 'shelve'` modules of python also offer some data storage functionality. Check them out some day too.

### 9.1.14 reading and writing excel files

## 9.2 Computational geometry

### 9.2.1 Changing coordinate systems

Let  $A, B, C$  be the unit cell vectors

1.  $A = A_1 x + A_2 y + A_3 z$
2.  $B = B_1 x + B_2 y + B_3 z$
3.  $C = C_1 x + C_2 y + C_3 z$

and we want to find the vector  $[s_1 \ s_2 \ s_3]$  so that

$$1. P = s1 A + s2 B + s3 C$$

where

$$1. P = [p1x + p2y + p3z]$$

if we expand 4), we get:  $s1 A1 x + s1 A2 y + s1 A3 z$

$$\bullet s2 B1 x + s2 B2 y + s2 B3 z$$

$$\bullet s3 C1 x + s3 C2 y + s3 C3 z = p1 x + p2 y + p3 z$$

If we now match coefficients on x, y, and z, we can write a set of linear equations as:

$$\begin{array}{ccc} A1 & B1 & C1 \\ A2 & B2 & C2 \\ A3 & B3 & C3 \end{array} \begin{array}{c} s1 \\ s2 \\ s3 \end{array} = \begin{array}{c} p1 \\ p2 \\ p3 \end{array}$$

or, in standard form:

$$\text{transpose}(A) s = p$$

and we need to solve for s as:

$$s = (A^T)^{-1} \cdot p$$

p must be a column vector, so we will have to transpose the positions provided by the atoms class, and then transpose the final result to get the positions back into row-vector form:

$$s = ((A^T)^{-1} p^T)^T$$

Here we implement that in code:

---

```

1 from ase import *
2 from ase.lattice.surface import *
3
4 np.set_printoptions(precision=3,suppress=True)
5
6 slab = fcc111('Pd',
7               a=3.92,          # Pd lattice constant
8               size=(2,2,3),    # 3-layer slab in 1x1 configuration
9               vacuum=10.0)
10
11 pos = slab.get_positions() #these positions use x,y,z vectors as a basis
12
13 # we want to see the atoms in terms of the unitcell vectors
14 newbasis = slab.get_cell()
15
16 s = np.dot(np.linalg.inv(newbasis.T),pos.T).T
17 print 'Coordinates in new bases are: \n',s
18
19 # what we just did is equivalent to the following atoms method
20 print 'Scaled coordinates from ase are: \n',slab.get_scaled_positions()

```

---

The method shown above is general to all basis set transformations. We examine another case next. Sometimes it is nice if all the coordinates are integers. For this example, we will use the bcc primitive lattice vectors and express the positions of each atom in terms of them. By definition each atomic position should be an integer combination of the primitive lattice vectors (before relaxation, and assuming one atom is at the origin, and the unit cell is aligned with the primitive basis!)

---

```

1  from ase.lattice.cubic import BodyCenteredCubic
2  from ase.calculators.jacapo import *
3
4  bulk = BodyCenteredCubic(directions=[[1,0,0],
5                                     [0,1,0],
6                                     [0,0,1]],
7                             size=(2,2,2),
8                             latticeconstant=2.87,
9                             symbol='Fe')
10
11
12  newbasis = 2.87*np.array([[ -0.5, 0.5, 0.5],
13                           [ 0.5, -0.5, 0.5],
14                           [ 0.5, 0.5, -0.5]])
15
16  pos = bulk.get_positions()
17
18  s = np.dot(np.linalg.inv(newbasis.T),pos.T).T
19  print 'atom positions in primitive basis'
20  print s
21
22  #let's see the unit cell in terms of the primitive basis too
23  print 'unit cell in terms of the primitive basis'
24  print np.dot(np.linalg.inv(newbasis.T),bulk.get_cell().T).T

```

---

### 9.2.2 Simple distances, angles

Scientific.Geometry contains several useful functions for performing vector algebra including computing lengths and angles.

---

```

1  import numpy as np
2  from Scientific.Geometry import *
3
4  A = Vector([1,1,1]) #Scientific
5  a = np.array([1,1,1]) #numpy
6
7  B = Vector([0.0,1.0,0.0])
8
9  print '|A| = ',A.length() #Scientific Python way
10 print '|a| = ',np.sum(a**2)**0.5 #numpy way
11 print '|a| = ',np.linalg.norm(a) #numpy way 2
12

```

---

---

```

13 print 'ScientificPython angle = ',A.angle(B) #in radians
14 print 'numpy angle = ',np.arccos(np.dot(a/np.linalg.norm(a),B/np.linalg.norm(B)))
15
16 #cross products
17 print 'Scientific A .cross. B = ',A.cross(B)
18 print 'numpy A .cross. B = ',np.cross(A,B) #you can use Vectors in numpy

```

---

### 9.2.3 Unit cell properties

The volume of a unit cell can be calculated from  $V = (a_1 \times a_2) \cdot a_3$  where  $a_1$ ,  $a_2$  and  $a_3$  are the unit cell vectors. It is more convenient, however, to simply evaluate that equation as the determinant of the matrix describing the unit cell, where each row of the matrix is a unit cell vector.

$$V = |\det(ucell)|$$

Why do we need to take the absolute value? The sign of the determinant depends on the handedness of the order of the unit cell vectors. If they are right-handed the determinant will be positive, and if they are left-handed the determinant will be negative. Switching any two rows will change the sign of the determinant and the handedness. :mod:`ase` implements a convenient function to get the volume of an :mod:`Atoms` object: :func:`ase.atoms.get\_volume`.

Here are three equivalent ways to compute the unit cell volume.

---

```

1 import numpy as np
2
3 a1 = [2, 0, 0]
4 a2 = [1, 1, 0]
5 a3 = [0, 0, 10]
6
7 uc = np.array([a1, a2, a3])
8
9 print np.dot(np.cross(a1,a2),a3)
10 print np.linalg.det(uc)
11
12 from ase import *
13
14 atoms = Atoms([],cell=uc) #empty list of atoms
15 print atoms.get_volume()

```

---

### 9.2.4 d-spacing

If you like to set up the vacuum in your slab calculations in terms of equivalent layers of atoms, you need to calculate the d-spacing for the hkl plane you are using. The script below shows several ways to accomplish that.

```

1  from ase import *
2  import numpy as np
3  from ase.lattice.cubic import FaceCenteredCubic
4
5  ag = FaceCenteredCubic(directions=[[1,0,0],
6                                     [0,1,0],
7                                     [0,0,1]],
8                           size=(1,1,1),
9                           symbol='Ag',
10                          latticeconstant=4.0)
11
12  # these are the reciprocal lattice vectors
13  b1,b2,b3 = np.linalg.inv(ag.get_cell())
14
15  '''
16   $g(111) = 1*b1 + 1*b2 + 1*b3$ 
17
18  and  $|g(111)| = 1/d_{111}$ 
19  '''
20  h,k,l = (1,1,1)
21  d = 1./np.linalg.norm(h*b1 + k*b2 + l*b3)
22
23  print 'd_111 spacing = %1.3f Angstroms' % d
24
25  #method #2
26  hkl = np.array([h,k,l])
27  G = np.array([b1,b2,b3]) #reciprocal unit cell
28
29  '''
30  Gstar is usually defined as this matrix of dot products:
31
32  Gstar = np.array([[dot(b1,b1), dot(b1,b2), dot(b1,b3)],
33                    [dot(b1,b2), dot(b2,b2), dot(b2,b3)],
34                    [dot(b1,b3), dot(b2,b3), dot(b3,b3)]])
35
36  but I prefer the notationally more compact:
37  Gstar = G .dot. transpose(G)
38
39  then,  $1/d_{hkl}^2 = hkl .dot. Gstar .dot. hkl$ 
40  '''
41
42  Gstar = np.dot(G,G.T)
43
44  id2 = np.dot(hkl,np.dot(Gstar,hkl))
45
46  print np.sqrt(1/id2)
47
48  # http://books.google.com/books?id=nJHSqEseuIUC&lpg=PA118&ots=YA9TBldoVH&dq=reciprocal%20metric%20tensor&pg=PA119#v=onepage&q=reciprocal%20metric%20tensor
49
50
51  '''Finally, many text books on crystallography use long algebraic
52  formulas for computing the d-spacing with sin and cos, vector lengths,
53  and angles. Below we compute these and use them in the general
54  triclinic structure formula which applies to all the structures.
55  '''
56  from Scientific.Geometry import Vector

```

```

57 import math
58
59 unitcell = ag.get_cell()
60 A = Vector(unitcell[0])
61 B = Vector(unitcell[1])
62 C = Vector(unitcell[2])
63
64 # lengths of the vectors
65 a = A.length()#*angstroms2bohr
66 b = B.length()#*angstroms2bohr
67 c = C.length()#*angstroms2bohr
68
69 # angles between the vectors in radians
70 alpha = B.angle(C)
71 beta = A.angle(C)
72 gamma = A.angle(B)
73
74 print '%1.3f %1.3f %1.3f %1.3f %1.3f %1.3f\n' % (a,b,c,
75                                                    alpha,beta,gamma)
76
77 h,k,l = (1,1,1)
78
79 from math import sin, cos
80
81 id2 = ((h**2/a**2*sin(alpha)**2
82        + k**2/b**2*sin(beta)**2
83        + l**2/c**2*sin(gamma)**2
84        +2*k*l/b/c*(cos(beta)*cos(gamma)-cos(alpha))
85        +2*h*l/a/c*(cos(alpha)*cos(gamma)-cos(beta))
86        +2*h*k/a/b*(cos(alpha)*cos(beta)-cos(gamma)))
87        /(1-cos(alpha)**2-cos(beta)**2 - cos(gamma)**2
88        +2*cos(alpha)*cos(beta)*cos(gamma)))
89
90 d = 1/math.sqrt(id2)
91
92 print d

```

---

2.30940107676

### 9.2.5 Center of mass

The center of mass is a convenient origin for many rotations, and moment of inertia calculations. The center of mass is computed from:

$$COM = \frac{\sum m_i \cdot r_i}{\sum m_i}$$

There is a convenience function for this: `:func: 'ase.atoms.get_center_of_mass'`

### 9.2.6 Moments of inertia

Moments of inertia are used in the rotational partition function in statistical mechanics. There is a convenience function for this: `:func: 'ase.atoms.get_moments_of_inertia'`.

Here are examples of using the function to calculate the moments of inertia for several types of molecules.

---

```
1 from ase import *
2 from ase.structure import molecule
3 from ase.units import *
4
5 print 'linear rotors: I = [Ia Ia 0]'
```

---

```
6 mlc = 'CO2'
7 atoms = molecule(mlc)
8
9 print ' %s moments of inertia: ' %(mlc), atoms.get_moments_of_inertia()
10 print
11
12 print 'symmetric rotors (IA = Ib) < Ic'
```

---

```
13 mlc = 'NH3'
14 atoms = molecule(mlc)
15 print ' %s moments of inertia: ' %(mlc), atoms.get_moments_of_inertia()
16
17 mlc = 'C6H6'
18 atoms = molecule(mlc)
19 print ' %s moments of inertia: ' %(mlc), atoms.get_moments_of_inertia()
20 print
21
22 print 'spherical rotors Ia = Ib = Ic'
```

---

```
23 mlc = 'CH4'
24 atoms = molecule(mlc)
25 print ' %s moments of inertia: ' %(mlc), atoms.get_moments_of_inertia()
26 print
```

---

## 9.3 Equations of State

The module :code:`ase.util.eos` uses a simple polynomial equation of state to find bulk unit cell equilibrium volumes and bulk modulus. There are several other choices you could use that are more standard in the literature. Here we summarize them and provide references to the relevant literature.

### 9.3.1 Birch-Murnaghan

This is probably the most common equation of state used most often, and is a modification of the original Murnaghan EOS described below. A current description of the equation is in reference [11]. You can also find the equations for the Vinet and Pourier-Tarantola equations of state in that reference.

Birch-Murnaghan EOS:

$$E(\eta) = E_0 + \frac{9B_0V_0}{16}(\eta^2 - 1)^2(6 + B'_0(\eta^2 - 1) - 4\eta^2)$$

where  $\eta = (V/V_0)^{1/3}$ ,  $B_0$  and  $B'_0$  are the bulk modulus and its pressure derivative at the equilibrium volume  $V_0$ . You may find other derivations of this equation in the literature too.

Two other equations of state in that reference are the Vinet EOS:

$$E(\eta) = E_0 + \frac{2B_0V_0}{(B'_0-1)^2} (2 - (5 + 3B'_0(\eta - 1))e^{-3(B'_0-1)(\eta-1)/2})$$

and the Poirier-Tarantola EOS:

$$E(\varrho) = E_0 + \frac{B_0V_0\varrho^2}{6} (3 + \varrho(B'_0 - 2))$$

with  $\varrho = -3 \ln(\eta)$ .

### 9.3.2 Murnaghan

The equation most often used in the Murnaghan [34] equation of state is described in [9].

$$E = E_T + \frac{B_0V}{B'_0} \left[ \frac{(V_0/V)^{B'_0}}{B'_0-1} + 1 \right] - \frac{V_0B_0}{B'_0-1}$$

where  $V$  is the volume,  $B_0$  and  $B'_0$  are the bulk modulus and its pressure derivative at the equilibrium volume  $V_0$ . All of these are parameters that are fitted to energy vs. unit cell volume ( $V$ ) data. When fitting data to this equation a guess of 2-4 for  $B'_0$  is usually a good start.

### 9.3.3 Birch

The original Birch equation [1] is:

$$E = E_0 + \frac{9}{8}B_0V_0 \left( \left( \frac{V_0}{V} \right)^{\frac{2}{3}} - 1 \right)^2 + \frac{9}{16}B_0V_0(B'_0 - 4) \left( \left( \frac{V_0}{V} \right)^{\frac{2}{3}} - 1 \right)^3$$

### 9.3.4 The Anton-Schmidt Equation of state [29]

$$E(V) = E_\infty + \frac{BV_0}{n+1} \left( \frac{V}{V_0} \right)^{n+1} \left( \ln \frac{V}{V_0} - \frac{1}{n+1} \right)$$

where  $E_\infty$  corresponds to the energy at infinite separation, although the model they use to derive this equation breaks down at large separations so this is usually not a good estimate of the cohesive energy.  $n$  is in the range of -2.

### 9.3.5 Fitting data to these equations of state

To use these equations of state to find the equilibrium cell volume and bulk modulus we need a set of calculations that give us the energy of the unit cell as a function of the cell volume. We then fit that data to one of the above equations to extract the parameters we want. All of these equations

of state are non-linear in the cell volume, which means you have to provide some initial guesses for the parameters.

Here we describe a strategy for getting some estimates of the parameters using a linear least squares fitting of a parabola to the data to estimate  $E_0$ ,  $V_0$ ,  $B$  and  $B'_0$  which are used as initial guess for a non-linear least squares fit of the equation of state to the data.

The following example illustrates one approach to this problem for the Murnaghan equation of state:

---

```

1  #!/usr/bin/env python
2
3  '''Example of fitting the Birch-Murnaghan EOS to data'''
4
5  from pylab import * #this includes numpy as np!
6  from scipy.optimize import leastsq
7
8  # raw data from 2.2.3-al-analyze-eos.py
9  v = np.array([13.72, 14.83, 16.0, 17.23, 18.52])
10 e = np.array([-56.29, -56.41, -56.46, -56.46, -56.42])
11
12 #make a vector to evaluate fits on with a lot of points so it looks smooth
13 vf = np.linspace(min(v),max(v),100)
14
15 ### fit a parabola to the data
16 # y = ax^2 + bx + c
17 a,b,c = polyfit(v,e,2) #this is from pylab
18
19 '''
20 the parabola does not fit the data very well, but we can use it to get
21 some analytical guesses for other parameters.
22
23 V0 = minimum energy volume, or where dE/dV=0
24 E = aV^2 + bV + c
25 dE/dV = 2aV + b = 0
26 V0 = -b/2a
27
28 E0 is the minimum energy, which is:
29 E0 = aV0^2 + bV0 + c
30
31 B is equal to V0*d^2E/dV^2, which is just 2a*V0
32
33 and from experience we know Bprime_0 is usually a small number like 4
34 '''
35
36 #now here are our initial guesses.
37 v0 = -b/(2*a)
38 e0 = a*v0**2 + b*v0 + c
39 b0 = 2*a*v0
40 bP = 4
41
42 #now we have to create the equation of state function
43 def Murnaghan(parameters,vol):
44 '''
```

```

45     given a vector of parameters and volumes, return a vector of energies.
46     equation From PRB 28,5480 (1983)
47     '''
48     E0 = parameters[0]
49     B0 = parameters[1]
50     BP = parameters[2]
51     V0 = parameters[3]
52
53     E = E0 + B0*vol/BP*((V0/vol)**BP)/(BP-1)+1) - V0*B0/(BP-1.)
54
55     return E
56
57     # and we define an objective function that will be minimized
58     def objective(pars,y,x):
59         #we will minimize this function
60         err = y - Murnaghan(pars,x)
61         return err
62
63     x0 = [e0, b0, bP, v0] #initial guesses in the same order used in the Murnaghan function
64
65     murnpars, ier = leastsq(objective, x0, args=(e,v)) #this is from scipy
66
67     #now we make a figure summarizing the results
68     plot(v,e,'ro')
69     plot(vfit, a*vfit**2 + b*vfit + c,'--',label='parabolic fit')
70     plot(vfit, Murnaghan(murnpars,vfit), label='Murnaghan fit')
71     xlabel('Volume ($AA^3$)')
72     ylabel('Energy (eV)')
73     legend(loc='best')
74
75     #add some text to the figure in figure coordinates
76     ax = gca()
77     text(0.4,0.5,'Min volume = %1.2f $AA^3$' % murnpars[3],
78         transform = ax.transAxes)
79     text(0.4,0.4,'Bulk modulus = %1.2f eV/$AA^3$ = %1.2f GPa' % (murnpars[1],
80                                                                    murnpars[1]*160.21773)
81         , transform = ax.transAxes)
82     savefig('images/a-eos.png')
83     show()
84
85     print 'initial guesses : ',x0
86     print 'fitted parameters: ', murnpars

```

---

You can see the Murnaghan equation of state fits the data better than the parabola.

Here is a comparison of the initial guesses and final parameters. You can see our guesses from the parabola were actually pretty good, and are the main reason we converged to a solution. If you try other guesses you will probably find the ‘`scipy.optimize.leastsq`’ function does not converge.

## 9.4 Miscellaneous jasp/Vasp tips

### 9.4.1 Using a special setup

Vasp provides [special setups](#) for some elements. The following guidelines tell you what is in a potential:

No extension means the standard potential `_h` means the potential is harder than the standard (i.e. needs a higher cutoff energy) `_s` means the potential is softer than the standard (i.e. needs a lower cutoff energy)

`_sv` *s* and *p* semi-core states are treated as valence states `_pv` *p* semi-core states are treated as valence states `_d` *d* semi-core states are treated as valence states

[1st row elements](#) [Alkali and alkali-earth metals](#) [d-elements](#) [p-elements](#) [f-elements](#)

Here we show how to select the `O_sv` potential in a calculation.

---

```

1 from ase import Atoms, Atom
2 from jasp import *
3
4 JASPRC['mode']='run'
5
6 atoms = Atoms([Atom('O',[5,5,5],magmom=1)],
7               cell=(6,6,6))
8
9 with jasp('molecules/O_sv',
10          encut=300,
11          xc='PBE',
12          ispin=2,
13          ismear=0,
14          sigma=0.001,
15          txt='O_test.txt',
16          setups={'O':'_sv'}, # specifies O_sv potential
17          atoms=atoms) as calc:
18
19     print atoms.get_potential_energy()

```

---

How do you know you got the right one? We can look at the first line of the POTCAR file in the calculation directory to see.

---

```

1 head -n 1 molecules/O_sv/POTCAR

```

---

## 9.4.2 Running jasp in parallel

jasp is smart. If you ask for more than one node, it will automatically try to run in parallel.

---

```

1 from jasp import *
2 JASPRC['queue.nodes']=4
3 from ase import Atom, Atoms
4 atoms = Atoms([Atom('O',[5,5,5],magmom=1)],
5               cell=(6,6,6))
6
7 with jasp('molecules/O_sv-4nodes',
8          encut=300,
9          xc='PBE',
10         ispin=2,
11         ismear=0,
12         sigma=0.001,
13         txt='O_test.txt',
14         setups={'O':'_sv'}, # specifies O_sv potential
15         atoms=atoms) as calc:
16
17     print atoms.get_potential_energy()

```

---

How do you know it ran on four nodes?

---

```
1 head molecules/0_sv-4nodes/OUTCAR
```

---

### 9.4.3 Exporting data json, xml, python, sqlite

jasp has some capability for representing a calculation result in an archival format. The formats currently under development are json, xml, python and sqlite. The main point of these methods is to make it easy to create archive files that are machine readable for supplementary information in publications. These are under development.

**python** This is code that should reconstruct the python code needed to run a particular calculation. There are some limitations, e.g. it does not currently get magnetic moments on the atoms.

---

```
1 from jasp import *
2
3 with jasp('bulk/alloy/cu') as calc:
4     print calc.python
```

---

#### json

---

```
1 from jasp import *
2
3 with jasp('bulk/alloy/cu') as calc:
4     print calc.json
```

---

**xml** This relies on the pyxser module.

---

```
1 from jasp import *
2
3 with jasp('bulk/alloy/cu') as calc:
4     print calc.xml
```

---

## 10 Python

### 10.1 TODO easy\_install as a user

This usually works if that directory is on your PYTHONPATH  
easy\_install -d ~/lib/python2.6/site-packages/ pymatgen

## 10.2 Integer division math gotchas

It pays to be careful when dividing by integers because you can get unexpected results if you do not know the integer division rules. In python 2.6, if you divide two integers, you get an integer! This is usually not a problem if there is no remainder in the division, e.g.  $6/3=2$ . But, if there is a remainder, and that remainder is important, you will lose it. Here is an example of calculating the mole fraction of a species from integer numbers of atoms in the unit cell. If you are not careful, you get the wrong answer! You can convert (also called casting) a number to a float using the float command.

---

```
1 nPd = 4
2 nCu = 5
3 x_Cu = nCu/(nPd + nCu)
4 print x_Cu
5
6 # now cast as floats
7 x_Cu = float(nCu)/float(nPd + nCu)
8 print x_Cu
```

---

Note that if one of the numbers is a float, python will automatically cast the integer as a float, and return a float.

---

```
1 nPd = 4
2 nCu = 5
3
4 # now cast as floats
5 x_Cu = float(nCu)/(nPd + nCu)
6 print x_Cu
```

---

Finally, you can tell python a number is a float by adding a decimal to it. You do not need to put a 0 after the decimal, but you can.

---

```
1 nPd = 4. # this is a float
2 nCu = 5
3
4 x_Cu = nCu/(nPd + nCu)
5 print x_Cu
```

---
